

Intelligent Reflecting Surface Assisted Beam Index-Modulation for Millimeter Wave Communication

Sarath Gopi and Sheetal Kalyani and Lajos Hanzo

Abstract—Millimeter wave communication is eminently suitable for high-rate wireless systems, which may be beneficially amalgamated with intelligent reflecting surfaces (IRS), while relying on beam-index modulation. Explicitly, we propose three different architectures based on IRSs for beam-index modulation in millimeter wave communication. Our schemes are capable of eliminating the detrimental line-of-sight blockage of millimeter wave frequencies. The schemes are termed as single-symbol beam index modulation, multi-symbol beam-index modulation and maximum-SNR single-symbol beam index modulation. The principle behind these is to embed the information both in classic QAM/PSK symbols and in the transmitter beam-pattern. Explicitly, we proposed to use a twin-IRS structure to construct a low-cost beam-index modulation scheme. We conceive both the optimal maximum likelihood detector and a low-complexity compressed sensing detector for the proposed schemes. Finally, the schemes designed are evaluated through extensive simulations and the results are compared to our analytical bounds.

Index Terms—Intelligent reflecting surfaces, beam index modulation, phased array antenna, compressed sensing.

I. INTRODUCTION

Next-generation systems are expected to satisfy substantially improved specifications. Furthermore, new solutions, such as the Internet of Things (IoT), massive machine type communications (MTC) also contribute to the escalating mobile data traffic, as predicted by the International Telecommunication Union (ITU) [1]. Hence researchers aim for increasing the degrees of design-freedom in support of these ambitious requirements.

The 30 – 300 GHz so-called millimeter wave (mmWave) frequency band has substantial hitherto unexploited bandwidth resources for supporting Gigabit per seconds (Gb/s) data rates [2]–[4]. For example, in indoor scenarios a data rate of upto 6.7 Gbps is

achieved by the IEEE 802.11ad standard developed at 60 GHz frequency [5]. This result has ignited research interest in this frequency range also for outdoor scenarios. In an early experiment, it has been shown that mmWave communication is capable of achieving a peak data rate of 1 Gbps in an outdoor environment for a communication range of upto 1.7 km at moderate Bit Error Rates (BERs) [6]. This system used only 500 MHz of bandwidth at 28 GHz. Naturally, there are a number of propagation challenges to be overcome, since typically only line-of-sight (LOS) communication is possible at these frequencies, which also suffer from fading, significant absorption losses in the atmosphere and building-penetration losses [7] [8].

Furthermore, researchers are also aiming for reducing both the power consumption and hardware cost. Intelligent Reflecting Surfaces (IRS) offer a viable solution for meeting these requirements [9]. Explicitly, IRSs constitute passive reflecting surfaces equipped with integrated electronic circuits, which are capable of imposing carefully controlled amplitude and/or phase shifts on the incident signals [10]–[12]. The concept has been earlier proposed in [13] and its employment as a phase-shifter has become popularized by [14]. IRSs are eminently suitable for energy-efficient solutions in a wide variety of applications, such as signal-to-noise-ratio (SNR) maximization [15], rate-maximization [16], [17], for improving the energy efficiency [18], [19], for minimizing transmit power [20], for providing secure communication [21], multi-cell MIMO communication [22], [23], over the air computation [24], low latency mobile edge computing [25], index modulation [26] and so on.

In [27], analog beamforming based beam-index modulation has been proposed as an extension of spatial modulation [28], [29]. Inspired by these results, we conceive IRS assisted beam-index modulation for mmWave communications. Beamforming techniques have been exploited in mmWave communication for mitigating their path loss [30]–[32], for achieving directional transmission [33]–[35], for avoiding inter-carrier-interference [36] and also for safeguarding against eavesdroppers [37]. However, there is a paucity of contributions on beamforming-aided index modulation in IRS-assisted mmWave communication. Our main contributions are:

TABLE I
COMPARISON OF THE PROPOSED SCHEME WITH SIMILAR IDEAS.

- 1) We propose IRS assisted beam index modulation for mmWave communication. Beamforming solutions proposed for mmWave frequencies tend to rely on either analog beamforming [41], [42] or on hybrid techniques [6], [39], [43]–[48]. In [49] digital beamforming is proposed, which relies on complex hardware. As a remedy, IRS has been proposed for imposing phase shifts on the incident signal, which can be exploited for beamforming. As a further benefit, they are capable of circumventing the predominantly LOS nature of mmWave propagation. Hence, our proposed scheme has at least three appealing features: it supports non-LOS communication at mmWave frequencies at a low cost, whilst conveying extra information via beam-index modulation.
- 2) We propose three different architectures for IRS assisted beam-index modulation. The first is termed as single-symbol beam index modulation, where the information is carried both by classic QAM/PSK symbols and by the transmitter beam-pattern. This idea has also been extended for further improving the data rate in our Scheme 2, which is a multi-symbol beam-index modulation arrangement. In the third scheme, we provide an architecture for improving the SNR of the proposed beam-index modulation.
- 3) The optimal maximum likelihood (ML) detector is derived for the schemes conceived. Additionally, a low complexity compressed sensing assisted detector is also developed.
- 4) An upper bound of the average BER is obtained for the optimal ML detector. Finally, the proposed scheme is evaluated through extensive simulations and its performance is compared to the theoretically obtained bound.

In Table I, we provide a bold summary and contrast our new contributions to the seminal literature. The key contribution of our scheme is a unique twin-IRS architecture, in which one of the IRSs can be positioned farther away from the transmitter. IM on this IRS is activated wirelessly using the other IRS. This architecture benefits in terms of accomplishing non-LOS communication by two LOS paths, additionally achieving a substantial beamformer gain and hence an SNR gain. The rest of the paper is organized as follows. Section II details the proposed IRS assisted beam-index

modulation schemes. The implementation aspects and parameter design of the schemes are detailed in Section III, while our detectors are developed in Section IV. In Section V, the error analysis of the proposed scheme is provided. Our simulation results are given in Section VI and we conclude in Section VII.

Notations: Throughout the paper, unless otherwise specified, bold lower case and bold upper case letters are used to represent vectors and matrices, respectively. \mathbf{A}^H , $\text{Tr}\{\mathbf{A}\}$ and $\lambda_{\min}(\mathbf{A})$ represents the hermitian, trace and minimum eigen value of \mathbf{A} , respectively. $\|\cdot\|$ stands for L_2 - norm. $|a|$ and $\Re\{a\}$ is the absolute and real value of scalar a , respectively. \mathbf{I} is the identity matrix of appropriate dimension. $\mathcal{CN}(\mu, \mathbf{C})$ represents the complex Gaussian distribution with mean vector μ and covariance matrix \mathbf{C} . $\lfloor b \rfloor$ is the largest integer not greater than b . $\Gamma(\cdot)$ is the Γ -function, i.e., $\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$ and for integer z , $\Gamma(z) = (z-1)!$ and $\Gamma(a, b)$ is the Gamma distribution with a and b are shape and rate parameters, respectively.

II. PROPOSED IRS ASSISTED BEAM-INDEX MODULATION SCHEMES

We propose three different IRS assisted beam-index modulation schemes. All these schemes are single input multiple output (SIMO) arrangements, containing a transmitter antenna (TA), two sets of IRSs and N_R receiver antennas (RAs). Each IRS has one or more reflecting surfaces (RS) and each RS has many elements. The first IRS, namely IRS_1 , can be directly accessed by the transmitter and it is used for selectively activating the elements in the second IRS, i.e. in IRS_2 . The block diagram of the proposed scheme is sketched in Fig. 1, which is further elaborated on using Fig. 2. The steps from ① to ⑤ in the Fig. 2 is detailed below.

- 1) The incoming bit sequence is split into two groups. The first group is used for selecting the classic PSK/QAM symbols, while the second set is used for beam-index modulation.
- 2) The TA and IRS_1 are kept close to each other. They have both wired and wireless connections. Based on the first group of bits, an appropriate PSK/QAM symbol (s) is selected at the transmitter, which is transmitted wirelessly to each RS in IRS_1 .

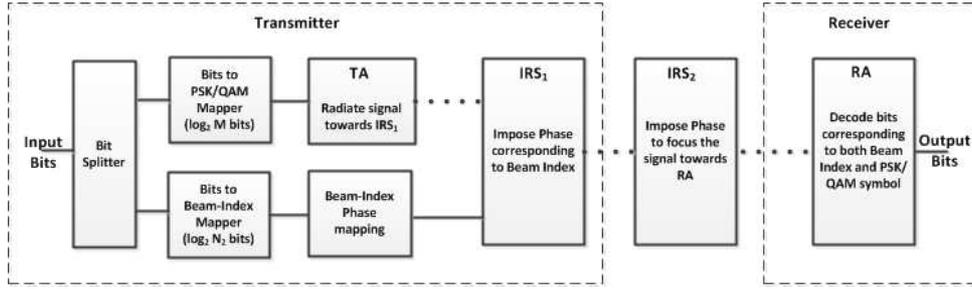

Fig. 1. Proposed IRS assisted beam-index modulation scheme. Solid and dotted lines indicate wired and wireless links, respectively.

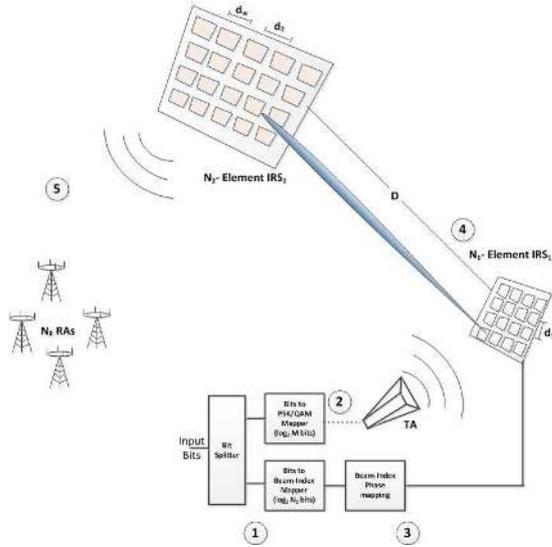

Fig. 2. Architecture of single-symbol beam-index modulation.

- 3) The wired connection is used for mapping the second group of bits onto beam-index modulation. These bits are converted to the appropriate phase vector, which are then forwarded to the elements of the RSs in IRS_1 .
- 4) Based on the received phase vector, the elements in IRS_1 impose the required phase shift on the incident signal, which are then forwarded to IRS_2 . The phase is specifically adjusted for ensuring that only the desired elements in IRS_2 receive the signal. This specific selection is determined based on the information bits reserved for beam-index modulation.
- 5) Each element of IRS_2 induce a constant phase to reflect the signal towards the RAs. This is captured by the RAs. The information detected at the RAs includes both the conventional PSK/QAM symbols and the specific element indices of IRS_2 , which reflect the symbols. This is done jointly by N_R RAs.

For detailing the schemes, we will make the following assumptions.

- 1) The channel between the TA and IRS_1 may be deemed to be a low-noise AWGN channel. A conventional horn antenna having a few centimetre

length can be used as the TA, where IRS_1 is positioned, say 4-5 m away from the TA [50]. Hence, the distance should satisfy the far field condition, albeit this is not actually necessary, since the position of the TA is perfectly known at IRS_1 , hence near-perfect delay compensation can be arranged for this location. The TA is designed in such a way that the signal is pointed exactly towards IRS_1 . Finally, IRS_1 , which is a passive device, introduces a phase shift and reflects the signal towards IRS_2 . Hence, the only source of noise, that can affect the signal is the one, which is added at IRS_1 , and this is negligible.

- 2) There is only LOS communication between IRS_1 and IRS_2 . Typically, a Rician channel model is used for modelling IRS-assisted communication systems [51]. However, for the proposed scheme the elements in IRS_1 adjust the phase in such a way that it forms a directional beam and only the specifically selected elements of IRS_2 receive the signal. Moreover, IRS_2 , which is close to IRS_1 , is carefully positioned for ensuring that there is no blockage between IRS_1 and IRS_2 . Hence, the channel between IRS_1 and IRS_2 is assumed to be an AWGN channel.
- 3) Between IRS_2 and the receiver, we have a Rician channel model.

A beneficial application of the proposed architectures can be found in the Internet of Things(IoT), where the desired information has to be collected by sensors and delivered to either a distant server or to a user. The various applications include smart homes, industrial and environmental monitoring, building and home automation etc. Let us assume that the information collected from a home or an industrial cite should be communicated to a BS, from where the information can be communicated to the destination through the cellular network. In this case, the TA and IRS_1 , which only belong to the specific user, can be placed in the terrace of the home or at the industrial cite. The IRS_2 can be situated at the top of a tall building in the vicinity, which can be shared among many such users, who have orthogonal resources. The details of the schemes are given below.

A. Scheme 1: Single-Symbol Beam-Index Modulation

This scheme is shown in Fig. 2. In this scheme, both the IRSs have only a single RS. IRS_1 is directly connected to the transmitter, whereas IRS_2 is kept at a distance, say D , from the first IRS. Let IRS_1 be a $(N_{1H} \times N_{1W})$ element array, while IRS_2 be an $(N_{2H} \times N_{2W})$ array and let $N_1 = N_{1H}N_{1W}$ and $N_2 = N_{2H}N_{2W}$ be the total number of elements in IRS_1 and IRS_2 , respectively. The TA sends the symbols to IRS_1 , where each element applies a specific phase shift to the incident wave so that only one of the elements in IRS_2 receives the signal. Hence, in this scheme the total number of bits per channel use (bpcu) is $\log_2 M + \lfloor \log_2 N_2 \rfloor$, where the first term corresponds to the QAM/PSK symbols, while the second term corresponds to the selection of the element in IRS_2 . Finally, IRS_2 reflects the signal and it is received at the RAs.

Let s be the transmitted symbol. The symbol received at IRS_1 is $s + w_1$, where $w_1 \sim \mathcal{CN}(0, \sigma_1^2)$. However, under Assumption 1, we have $\sigma_1^2 \approx 0$ and the contribution w_1 can be discarded. Therefore, the vector received at IRS_2 is:

$$\mathbf{x}_2 = \mathbf{b}s + \mathbf{w}_2, \quad (1)$$

where $\mathbf{w}_2 \sim \mathcal{CN}(0, \sigma_2^2)$ under Assumption 2) and \mathbf{b} is an $N_2 \times 1$ vector. Ideally, \mathbf{b} should have only a single non-zero entry corresponding to the index of the beam (or equivalently corresponding to the selected element in IRS_2). However, this will not happen in practice, since a finite power will be dispersed on other directions also and this power distribution depends on the beampattern. The vector at the receiver can be written as:

$$\begin{aligned} \mathbf{y} &= \mathbf{H}\Theta\mathbf{x}_2 + \mathbf{w}_R \\ &= \mathbf{H}\Theta\mathbf{b}s + \mathbf{w}, \end{aligned} \quad (2)$$

where \mathbf{H} is the $N_R \times N_2$ channel matrix as defined under Assumption 3, Θ is an $(N_2 \times N_2)$ diagonal matrix of phase shifts given by the elements in IRS_2 and $\mathbf{w}_R \sim \mathcal{CN}(0, \sigma_R^2)$. Note that $\mathbf{w} = \mathbf{H}\Theta\mathbf{w}_2 + \mathbf{w}_R$ is the additive noise component having a distribution of $\mathcal{CN}(0, \Sigma)$, where $\Sigma = \mathbf{H}\mathbf{H}^H\sigma_2^2 + \sigma_R^2\mathbf{I}$. Finally, the receiver has to detect both \mathbf{b} and s from \mathbf{y} to decode the transmitted bits. The detection schemes will be discussed in Section IV.

This scheme predominantly uses only a fraction of elements of the second reflecting surface, instead of exploiting all of them to improve the attainable beamformer gain. However, it should be noted that most of the transmitted energy is focussed on the intended elements, while the power impinging on all other elements is negligibly small, since beamforming is used in the first stage. Hence, with the aid of the proposed scheme, we will get the dual advantages of both a beneficial beamforming gain and the additional advantage of an increased data rate.

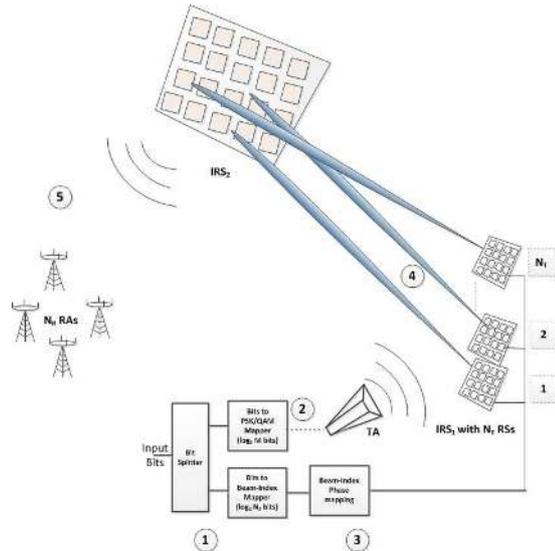

Fig. 3. Architecture of multi-symbol beam-index modulation. Contrast to Fig. 2, there are N_T RSs in IRS_1 in this case.

B. Scheme 2: Multi-Symbol Beam-index Modulation

In the second scheme, the first scheme is extended to multi-symbol communication. The architecture is shown in Fig. 3. In this case, there are N_T RSs in IRS_1 contrast to a single RS in Scheme 1. The modulator identifies N_T different phase-vectors depending on the bit sequence corresponding to the beam-index modulation and each vector is fed to different RSs in IRS_1 . Therefore, N_T RSs focus the conventional QAM/PSK symbol onto N_T different elements of IRS_2 . Hence, in this case, the total number of bpcu is $\log_2 M + \left\lfloor \log_2 \binom{N_2}{N_T} \right\rfloor$. Therefore, this scheme provides a higher data rate than scheme 1. The choice of the elements to be activated can be organized using a look up table method or the combinatoric approach [52], [53].

Mathematically, this scheme can be represented using Equations (1) and (2). However, the difference is that in this case, ideally there will be N_T non-zero entries in \mathbf{b} .

C. Scheme 3: Maximum-SNR Single-Symbol Beam-Index Modulation

Fig. 4 shows the architecture of this scheme. This is similar to Scheme 1, except that in this case each element of IRS_2 is replaced by an RS having N_3 elements. Hence, there will be a total of N_2N_3 elements in IRS_2 . Both the TA and IRS_1 function in the same way as in the case of single-symbol beam-index modulation. Hence, the signal received at IRS_2 can be written using (1). However, in contrast to the other two cases, here the elements in IRS_2 apply a phase shift to the incident signal. The phase shift in IRS_2 is adjusted in such a way that the SNR at the receiver is maximized.

Note that in (2) \mathbf{H} and Θ is an $(N_R \times N_2N_3)$ and $(N_2N_3 \times N_2N_3)$ matrix, respectively in this case. Fur-

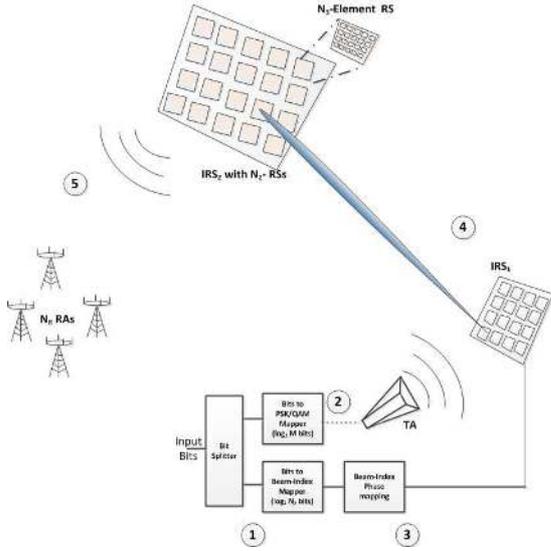

Fig. 4. Architecture of the Maximum-SNR Single-Symbol Beam-Index Modulation. Contrast to Fig. 2, there are N_3 elements in each RS of IRS_2 , which impose phase shift on the incident signal to maximize SNR at the RAs.

thermore, Θ is not a constant matrix, but depends on \mathbf{H} . The overall SNR in this case is defined as:

$$\text{SNR} = \frac{\|\mathbf{H}\Theta\mathbf{b}_s\|^2}{\text{Var}(\|\mathbf{w}\|)}, \quad (3)$$

where the denominator is the variance of the norm of the vector \mathbf{w} . The SNR can be maximized by maximizing the numerator of (3), since the denominator is independent of Θ , which is the maximization variable. Let $\theta_{1:N_2N_3}$ represents the entries of the diagonal of Θ . Hence, the SNR maximization can be written as:

$$\max_{\theta_l} \|\mathbf{H}\Theta\mathbf{b}_s\|^2 \quad s.t. \quad |\theta_l| = 1, \forall l = 1, 2, \dots, N_2N_3. \quad (4)$$

However, the above optimization problem has the following challenges. IRS_2 is a passive device and it may not be practical to solve a complex optimization problem there. Hence, the optimization should ideally be carried out at transmitter or receiver and the resultant information has to be communicated to IRS_2 . Therefore, if the optimization depends on the data to be transmitted (\mathbf{b}_s), Θ has to be updated in every time slot, which is a substantial communication overhead. Hence, the optimization should preferably only depend on either an average value of \mathbf{b}_s or indeed ideally should be independent of it. Accordingly, we will propose the following solutions for (4).

1) *Solution 1*: This solution is based on the assumption that an ideal beam pattern exists, i.e., all elements in the selected RS of IRS_2 receives the same power, while all other elements receive no power. Without loss of generality, let this constant be 1. Hence, the optimization function in (4) can be written as:

$$\|\mathbf{H}\Theta\mathbf{b}_s\|^2 = \|\mathbf{H}\Theta\mathbf{1}\|^2 = \|\mathbf{H}\theta\|^2, \quad (5)$$

where $\mathbf{1}$ is a vector of 1s and θ is a vector formed from the diagonal elements $\theta_{1:N_2N_3}$ of Θ . Hence, the maximization problem (4) becomes:

$$\max_{\theta_l} \theta^H \mathbf{H}^H \mathbf{H} \theta \quad s.t. \quad |\theta_l| = 1, \forall l = (\hat{I}-1)N_3 + 1, \dots, \hat{I}N_3, \quad (6)$$

where \hat{I} is the specifically selected RS in IRS_2 . Let $\theta_l = e^{j\alpha_l}$, since $|\theta_l| = 1$. Bearing this in mind and noting that $\mathbf{H}^H \mathbf{H}$ is a Hermitian matrix, (4) is reformulated as the following unconstrained optimization problem.

$$\max_{\alpha_l} \sum_{i=(\hat{I}-1)N_3+1}^{\hat{I}N_3} \sum_{j=(\hat{I}-1)N_3+1}^{\hat{I}N_3} \mathcal{R}e \left\{ e^{j(\alpha_i - \alpha_j)} (\mathbf{H}^H \mathbf{H})_{ij} \right\}, \quad (7)$$

where $(\mathbf{H}^H \mathbf{H})_{ij}$ is the $(i, j)^{th}$ element of $\mathbf{H}^H \mathbf{H}$. Since (7) is not a concave function, it can only be solved using some iterative technique for finding its local maximum.

2) *Solution 2*: This solution relies on the assumption that $N_R \geq N_3$, i.e. there are more number of RAs than the number of elements in the RS of IRS_2 . In order to develop the solution, let us state and prove Lemma 1.

Lemma 1. Let \mathbf{H}_Q and Θ_Q be the $(N_R \times N_3)$ and $(N_3 \times N_3)$ sub-matrices of \mathbf{H} and Θ corresponding to the selected RS, respectively and let \mathbf{b}_Q be the corresponding sub-vector of \mathbf{b} . If $N_R \geq N_3$, with probability 1, the bound

$$\|\mathbf{H}_Q \Theta_Q \mathbf{b}_Q s\|^2 \geq \lambda_{\min} \left(\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q \right) \text{Tr} \{ (\mathbf{b}_Q s)(\mathbf{b}_Q s)^H \} \quad (8)$$

is non-trivial, which equivalently leads to $\lambda_{\min} \left(\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q \right) > 0$.

Proof. See Appendix A for proof. \square

Lemma 1 can be used for solving the optimization problem (4). The idea is to maximize the non-trivial lower bound instead of the actual function. Hence, the optimization problem (4) becomes:

$$\max_{\theta_l} \lambda_{\min} \left(\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q \right) \quad s.t. \quad |\theta_l| = 1, \forall l = (\hat{I}-1)N_3 + 1, \dots, \hat{I}N_3. \quad (9)$$

We know that $\lambda_{\min}(\mathbf{A}) = \min_{\|\mathbf{z}\|=1} \|\mathbf{A}\mathbf{z}\|$ [54, Eq. 7.5.4]. Therefore (9) can be rewritten as:

$$\max_{\theta_l} \min_{\mathbf{z}} \|\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q \mathbf{z}\| \quad s.t. \quad \|\mathbf{z}\| = 1, \quad |\theta_l| = 1, \forall l = (\hat{I}-1)N_3 + 1, \dots, \hat{I}N_3, \quad (10)$$

where (10) is a constrained non-linear minimax optimization problem. This can be solved directly [55], [56]. Alternatively, it can be converted into a non-linear maximization problem by introducing an additional variable and then solved using standard techniques.

It should be noted that in both solutions of the SNR maximization problem, \hat{I} , i.e. the selected data dependent RS of IRS_2 that has to be optimized, depends on the information bits. In order to avoid the dependence of optimization on the information bits, each RS is optimized separately whenever there is considerable change in the channel. The optimized phase information is passed to IRS_2 , which applies phase shifts to all elements instead of the selected RS. This scheme can be extended to the case of multi-symbol beam-index modulation (Scheme 2), where there will be N_T RSs in IRS_1 , which activate N_T RSs in IRS_2 . Finally, all the activated RSs in IRS_2 can apply a phase shifts for improving the SNR. Thus the scheme will have both an improved data rate and improved SNR. Practically, the optimal phase shifts have to be estimated at the receiver and then communicated to IRS_2 whenever there is significant change in the channel characteristics.

III. IMPLEMENTATION OF BEAM-INDEX MODULATION

The principle behind the proposed beam-index modulation is the data-dependent activation of the elements in IRS_2 . This is achieved by appropriately choosing the phase shifts applied by the elements in IRS_1 . In order to estimate the phase shifts, it is assumed that there is only LOS communication between IRS_1 and IRS_2 . Therefore, the phase shifts only depend on the geometry of the pair of IRSs. The estimation of phase shifts is detailed below.

Let the centre of IRS_1 be the origin co-ordinate $(0, 0, 0)$ and \mathbf{P} be the position vector of elements of IRS_1 . Let the n^{th} element of IRS_2 be activated by IRS_1 according to the input bit sequence and let (ϕ_n^h, ϕ_n^v) represents the azimuth and the elevation angle pair for this element with respect to the origin. Then, the phase-vector to be given by the elements of IRS_1 to choose the n^{th} beam is $\psi = 2\pi f\tau$, where $\tau = \frac{\mathbf{P}^H \mathbf{u}_n}{c}$ with c and f being the speed of the light and the carrier frequency, and $\mathbf{u}_n = (\sin \phi_n^h \cos \phi_n^v \cos \phi_n^h \cos \phi_n^v \sin \phi_n^v)$. Finally, in the case of multi-bit beam-index modulation, these phase shifts have to be calculated for each of IRSs according to the input bit sequences.

Additionally, if the IRS elements can modify the amplitude of the incident signal along with the phase, one can modify the relative weighting of each element. Since IRSs constitute passive devices, amplification may be difficult to achieve and will not be a cost effective solution. However, attenuation can be readily applied to the incident signal [57]. The attenuation can be adjusted in such a way that it acts as a window function for the beamforming and the beam pattern can be accordingly modified. This will help in reducing the interference, which will be discussed in Section V. In Section III-A, the design of two IRSs is detailed.

A. Parameter Design

The parameters to be designed are the number of elements and the corresponding inter-element spacing in IRS_1 , as well as in IRS_2 and the distance between two IRSs. Let λ be the wavelength corresponding the highest frequency of operation. We will fix the design parameters as follows [58].

- 1) *Inter-element spacing in IRS_1 (d_1):* The elements in each RSs of IRS_1 should be spaced at $\frac{\lambda}{2}$ distances. For example, if the maximum operating frequency is $f_{max} = 60$ GHz, then the spacing between the elements in IRS_1 is $d_1 = 2.5$ mm. Now, if IRS_1 is a 100×100 element system, then its dimension is going to be as compact as 0.25×0.25 m. This spacing is important for avoiding grating lobes in the beams formed using IRS_1 [58, eq. 2.117].
- 2) *Distance between two IRSs (D):* The distance (D) between IRS_1 and IRS_2 should meet the far field condition of $D > \frac{2L^2}{\lambda}$, where L is the length of the RS [59, pp. 32]. In the above example $D > 25$ m. If this condition is met, it can be assumed that the wave front travelling from IRS_1 to IRS_2 is planar, so that the phase shifts can be computed as detailed in Section III.
- 3) *Inter element spacing in IRS_2 (d_2):* The width of each element in IRS_2 (d_w) should be less than $D\theta_{BW}$, where θ_{BW} is the beam-width of IRS_1 and the separation d_2 between elements in IRS_2 should be higher than this value. These conditions ensure that the intended element and *only the intended element* receives the signal reflected by IRS_1 . For a rectangular window, the approximate beam-width is $\theta_{BW} \approx \frac{50\lambda}{L}$ [58, Eq. (2.100)]. In the example we have considered $\theta_{BW} \approx 1^\circ$ corresponding to the minimum frequency. Therefore $d_w < 48$ cm and $d_2 > 48$ cm for $D = 25$ m. Now, if $N_{1H} = N_{1W} = 8$, IRS_2 has an approximate dimension of 4 m \times 4 m.
- 4) *Number of elements in IRS_1 (N_1):* The number of elements in IRS_1 determines the length L of the array and its beam-width θ_{BW} , where these parameter decide the spacing between two IRSs and the inter-element spacing in IRS_2 . A larger value of N_1 with accurate phase shifting and a larger value of d_2 direct the beam to the desired direction, hence reducing the potential beam mis-alignment problem of our beam index modulation scheme.
- 5) *Number of elements in IRS_2 (N_2):* This determines the data rate of the system. A large value of N_2 gives a higher data rate. However, this will make the size of IRS_2 large. Hence, N_2 is restricted by the maximum affordable array dimension.

IV. DETECTOR

The detector has to recover the bits embedded both into the QAM/PSK symbol and the TA activation pattern in IRS_2 . Explicitly, it has to detect s and \mathbf{b} from \mathbf{y} in (2). Let $\mathbf{x} = \mathbf{b}s$ and $\mathbf{A} = \mathbf{H}\Theta$. Now, (2) can be written as:

$$\mathbf{y} = \mathbf{A}\mathbf{x} + \mathbf{w}. \quad (11)$$

It is assumed that \mathbf{A} is known at the receiver.

A. Optimal Detector

We first derive the optimal ML detector for the single symbol cases, i.e. for Scheme 1 and Scheme 3. Then we extend it to the multi symbol case of Scheme 2.

1) *Single-Symbol Schemes*: Consider the vector \mathbf{x} in (11). Ideally in single-symbol schemes only one of the entries in \mathbf{x} should be a non-zero value, since only one element receives the symbol. However, this will not be the case in practice, since the beamformer will introduce a non-zero power also in directions other than the required one. Hence, practically more than one element of IRS_2 receives the symbol. However, the power in the undesired beam-indices is much lower than that in the intended index and these powers depend on the beampattern of IRS_1 . The data-dependent beam-index changes can be represented approximately by a beampattern rotation. Hence, (11) can be written as:

$$\mathbf{y} = \mathbf{A}\Pi_{\mathbf{p}} + \mathbf{w}, \quad (12)$$

where \mathbf{p} represents the vector of powers in the various indices of \mathbf{x} and $\Pi_{\mathbf{p}}$ represents a particular permutation of the power pattern. Therefore, in order to identify the beam-index, we have to identify the power pattern permutation $\Pi_{\mathbf{p}}$. Now, $\mathbf{y} \sim \mathcal{CN}(\mathbf{A}\Pi_{\mathbf{p}}, \Sigma)$. Hence, the ML detector of this problem is formulated as:

$$\begin{aligned} & \min_{\Pi_{\mathbf{p}}} (\mathbf{y} - \mathbf{A}\Pi_{\mathbf{p}})^H \Sigma^{-1} (\mathbf{y} - \mathbf{A}\Pi_{\mathbf{p}}) \\ \Rightarrow & \max_{\Pi_{\mathbf{p}}} \mathcal{R}e \left\{ \left(\mathbf{y} - \frac{1}{2}\mathbf{A}\Pi_{\mathbf{p}} \right)^H \Sigma^{-1} \mathbf{A}\Pi_{\mathbf{p}} \right\}. \end{aligned} \quad (13)$$

In general, the search problem (13) is NP-hard. However, in our case, there are only N_2M different patterns corresponding to N_2 different beam indices and M QAM/PSK symbols. Hence, a moderate-complexity search will give the optimal solution to (13).

2) *Multi-Symbol Scheme*: The ML detector (13) is also suitable for multi-symbol case. However, in this case, since there are N_T desired beam-indices at a time, which interact with each other and thereby produce a large number of possible combinations $\Pi_{\mathbf{p}}$. Explicitly, $\binom{N_2}{N_T}M$ different patterns hypothesis must be tested for N_T RSs in IRS_1 . Hence the ML detector may no longer be a computationally tractable solution. Hence, in Section IV-B, we will be proposing a suboptimal

compressed sensing (CS) aided detector, which can be used for any of the proposed schemes at a lower computational complexity.

B. Suboptimal Compressed Sensing Detector

The transmitted vector \mathbf{x} in (11) is sparse, when the number of active elements (i.e., elements that receive the symbol) is much less than the total number of elements in IRS_2 . Therefore, one can use an efficient sparse reconstruction algorithm [60], [61] for identifying the non-zero components in \mathbf{x} , which can be used to estimate \mathbf{b} . However, it should be noted that for the successful recovery of the sparse vector \mathbf{x} , there should be a sufficient number of measurements. This can be either achieved by having a sufficient number of RAs (N_R should be sufficiently large) or taking multiple measurements, which would naturally reduce the data rate. Finally, s is obtained from the estimated \mathbf{b} as:

$$\hat{s} = \min_{s \in \mathcal{M}} \|\mathbf{y} - \mathbf{b}s\|^2, \quad (14)$$

where \mathcal{M} is the constellation used.

C. Complexity

The optimal ML detector has to compute (13) for all possible combinations, which requires approximately on the order of $(N_R^3 + N_R N_2)$ multiplications. This has to be done for each possible symbol. For the multi-symbol case, there are $\binom{N_2}{N_T}M$ possible symbols. Hence, the total computational complexity is approximately on the order of $\binom{N_2}{N_T}M(N_R^3 + N_R N_2)$, which reduces to the order of $N_2 M(N_R^3 + N_R N_2)$ for single-symbol cases. On the other hand, if a greedy compressed sensing based suboptimal algorithm is used, the complexity will be reduced to the order of $N_2 N_R N_T$, which is much lower than that of the optimal ML detector.

V. AVERAGE BIT ERROR RATE ANALYSIS

In this section, we will estimate an upper bound for the average bit error rate (BER) of the optimal ML detector of Section IV-A. Let $\Pr \left\{ \Pi_{\mathbf{p}}^i \rightarrow \Pi_{\mathbf{p}}^j \right\}$ represent the probability that the pattern $\Pi_{\mathbf{p}}^i$ is identified as $\Pi_{\mathbf{p}}^j$ and $v_{i,j}$ represent the number of bits in error between the two permutations $\Pi_{\mathbf{p}}^i$ and $\Pi_{\mathbf{p}}^j$. Then the average BER is formulated as:

$$\text{BER} = \sum_{i=1}^{\Omega} \sum_{\substack{j=1 \\ j \neq i}}^{\Omega} \frac{v_{i,j}}{n_b \Omega} \Pr \left\{ \Pi_{\mathbf{p}}^i \rightarrow \Pi_{\mathbf{p}}^j \right\}, \quad (15)$$

where n_b is the total number of bits per channel use and Ω is the total number of possible permutations. Equation (15) assumes that all permutations are equally likely. The probability of symbol error $\Pr \left\{ \Pi_{\mathbf{p}}^i \rightarrow \Pi_{\mathbf{p}}^j \right\}$

in (15) can be found as follows. When $\Pi_{\mathbf{p}}^i$ is transmitted, the detector identifies $\Pi_{\mathbf{p}}^j$ as the transmitted symbol based on:

$$\arg \max_k \mathcal{R}e \left\{ \left(\mathbf{y} - \frac{1}{2} \mathbf{A} \Pi_{\mathbf{p}}^k \right)^H \Sigma^{-1} \mathbf{A} \Pi_{\mathbf{p}}^k \right\} = j, \quad (16)$$

where \mathbf{y} is given in (12) in conjunction with $\Pi_{\mathbf{p}} = \Pi_{\mathbf{p}}^i$. Let us define $r_k = \mathcal{R}e \left\{ \left(\mathbf{y} - \frac{1}{2} \mathbf{A} \Pi_{\mathbf{p}}^k \right)^H \Sigma^{-1} \mathbf{A} \Pi_{\mathbf{p}}^k \right\}$. Hence, we have

$$\Pr \left\{ \Pi_{\mathbf{p}}^i \rightarrow \Pi_{\mathbf{p}}^j \right\} = \Pr \left\{ \bigcap_{k \neq j} r_j > r_k \right\}. \quad (17)$$

The computation of the probability of intersection of the event in (17) is very difficult. Hence, it is bounded using Fretchet's inequality [62] as follows:

$$\Pr \left\{ \bigcap_{k \neq j} r_j > r_k \right\} \leq \min_k \Pr \{ r_j > r_k \}. \quad (18)$$

In order to estimate the bound, the probabilities of $\Pr \{ r_j > r_k \}$ have to be calculated for each $k \neq j$. Theorem 1 stated below gives an expression of the probability $\Pr \{ r_j > r_k \}$.

Theorem 1. Let us assume the Rician channel model with $\mathbb{E}\{\mathbf{H}\} = \bar{\mathbf{H}}$ and that the row vectors of \mathbf{H} are independent and identically distributed with covariance matrix $\bar{\Sigma}_c$ and also let $\sigma_2^2 \ll \sigma_R^2$. When $\Pi_{\mathbf{p}}^i$ is the actual signal transmitted and Θ is a constant matrix independent of \mathbf{H} , the probability of the events $r_j > r_k$, i.e. $\Pr \{ r_j > r_k \}$ can be approximated as:

1) For $k = i$:

$$\Pr \{ r_j > r_i \} = \frac{1}{2} \left[1 - \sqrt{\frac{\beta_1}{1 + \beta_1}} \sum_{n=0}^{N_R - 1} \binom{2n}{n} \left(\frac{1}{4(1 + \beta_1)} \right)^n \right], \quad (19)$$

$$\text{where } \beta_1 = \frac{(\Pi_{\mathbf{p}}^i - \Pi_{\mathbf{p}}^j)^H \Theta^H (\bar{\Sigma}_c + \frac{1}{N_R} \bar{\mathbf{H}}^H \bar{\mathbf{H}}) \Theta (\Pi_{\mathbf{p}}^i - \Pi_{\mathbf{p}}^j)}{4\sigma_R^2}.$$

2) For $k \neq i$ and when $q_R = \mathcal{R}e\{q\} \neq 0$, where q is defined in (48):

$$\Pr \{ r_j > r_k \} = \frac{1}{2} \left[1 - \frac{1}{2} \sqrt{\frac{\beta_2}{1 + \beta_2}} \sum_{n=0}^{N_R - 1} \binom{2n}{n} \left(\frac{1}{4(1 + \beta_2)} \right)^n \right], \quad (20)$$

$$\text{where } \beta_2 = \frac{q_R^2}{(2 + \sigma_k^2) \sigma_{z_1}^2} \text{ and the constants } \sigma_{z_1}^2 \text{ and } \sigma_k^2 \text{ are defined in (46) and (54), respectively.}$$

3) For $k \neq i$ and when $q_R = 0$, $\Pr \{ r_j > r_k \} = \frac{1}{2}$.

Proof. See Appendix B for proof. \square

Finally, for each transmitted symbol $\Pi_{\mathbf{p}}^i$, the minimum value of $\Pr \{ r_j > r_k \}$, $\forall k \neq j$ is computed using Theorem 1 and it is substituted for $\Pr \left\{ \Pi_{\mathbf{p}}^i \rightarrow \Pi_{\mathbf{p}}^j \right\}$ into (15) for achieving the bound of the average BER. Note that (19) and (20) also hold for the Rayleigh channel, in which case the matrix $\left(\bar{\Sigma}_c + \frac{1}{N_R} \bar{\mathbf{H}}^H \bar{\mathbf{H}} \right)$ is replaced by \mathbf{I} to calculate β_1 and β_2 .

The bounds derived for the average BER can be used for both Scheme 1 and Scheme 2. In the case of Scheme 1 $\Omega = N_2 M$ and $n_b = \log_2 M + \lceil \log_2 N_2 \rceil$, whereas for Scheme 2, the corresponding values are $\Omega = \binom{N_2}{N_T} M$ and $n_b = \log_2 M + \left\lceil \log_2 \binom{N_2}{N_T} \right\rceil$. For Scheme 3, Θ is no longer independent of $\bar{\mathbf{H}}$ and therefore the bounds in Theorem 1 do not hold. However, the conditional probabilities derived in Appendix C can be used for Scheme 3 also. Based on this the unconditional probabilities can be derived using sampling method for computing the bound.

VI. SIMULATION RESULTS

Extensive simulations have been carried out to establish the performance of the proposed scheme on the system parameters. Explicitly, we studied the average BER of the proposed schemes vs. the SNR, the number of elements (N_2) in IRS_2 , the number of receivers (N_R), the number of RSs in IRS_1 and the Rician factor, denoted by K . We have considered both the optimal ML detector and the low complexity compressed sensing detector in our performance evaluation. The system parameters used are given below.

- IRS_1 : A 100×100 rectangular array with spacing 2.5 mm . This corresponds to half wavelength of the frequency.
- Distance between IRSs (D): 30 m . This distance satisfies the far-field condition for IRS_1 .
- IRS_2 : In general, an 8×8 rectangular array is used with inter element spacing of $d_2 = 60 \text{ cm}$. However, these parameters are changed for the various performance studies, which is mentioned in the corresponding discussions.

We used 16 level QAM at 60 GHz in all simulations. The results are shown in Fig. 6-9 for 10^5 Monte Carlo runs. We used both Rician and Rayleigh fading channels. Throughout the simulations, it is assumed that the channel is perfectly known at the receiver. Channel estimation in IRS-aided systems is quite a challenge, since the IRS is passive and has no signal processing capability. However, the schemes adopted in [51], [63] could be used as a solution to the channel estimation problem.

In Fig. 6-Fig. 10, the proposed schemes 1 and 2 are referred as $S1$ and $S2$, respectively. $S3$ represents the solution of (4), whereas $S301$ and $S302$ represent the solution of (7) and (10), respectively. $S1\text{-Err}$ represents the results of the proposed scheme 1 in the presence of channel estimation errors. ML and CS represent the results of optimal ML and compressed sensing based detectors, respectively and UB, the theoretical upper bound given in (18).

Fig. 5 shows the performance of scheme $S1$ at various SNRs for different values of the Rician factor (K). Observe from Fig. 5 that the performance of the low-complexity CS detector is inferior to that of the ML detector. As for the ML detector, the average

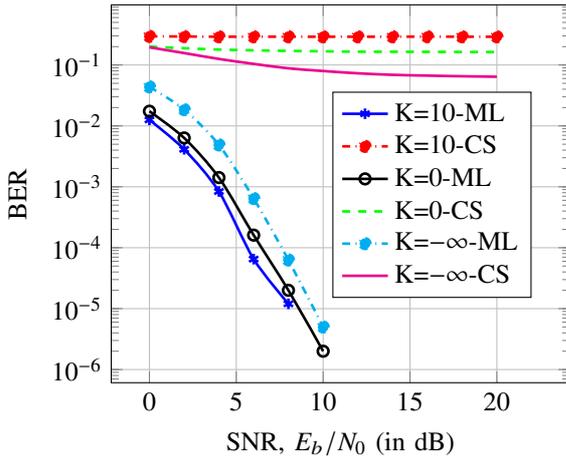

Fig. 5. S1: Comparison of ML and CS detectors by simulations. K is the Rician factor in dB

BER tends to zero above 10 dB SNR, whereas it exhibits an error floor near 0.1 for the CS detector. The performance of the CS detector is improved, when the Rician factor K decreases. This is because as K decreases, the projection matrix \mathbf{A} of the signal recovery becomes more random and the restricted isometric property [64] is improved and it is best for the Rayleigh channel. However, the performance of the ML detector is improved with K , since the LOS component is increased with K . This is also reflected by the upper bound seen in Fig. 6.

Fig. 6 shows the performance of single-symbol beam-index modulation (S1) against the Rician factor (K) for different SNRs. The average BER obtained through simulations is compared against the upper bound derived in Section V. The BER improvement vs. K is due to increasing the LOS component. However, the variation in BER is only moderate, because the SNR is kept constant upon increasing K . Furthermore, the optimal ML detector has perfect channel knowledge. However, as K increases, the gap between the simulation results and the corresponding upper bound is reduced. This is also observed at high SNRs. Therefore, it can be concluded that for both these cases, our bound becomes tighter.

The performance of the CS detector can be improved by increasing the number of RAs as shown in Fig. 7, where the average BER is plotted against N_R . This is plotted for Rayleigh channel, which gives the best performance for CS detector. The curves are shown for different number of elements in IRS_2 (i.e. N_2). Observe that for the same number of RAs, the performance degrades, as N_2 increases. However, as N_2 increases, the data rate will increase.

Fig. 8 compares the ML detector's performance for the three proposed schemes in terms of their average BER for Rician factor $K = 0$ dB . For S2, we used $N_T = 2$, i.e. the number of RSs in IRS_1 is two. This is because, if N_T is large, the complexity of optimal ML decoding will escalate. For fair comparison, the

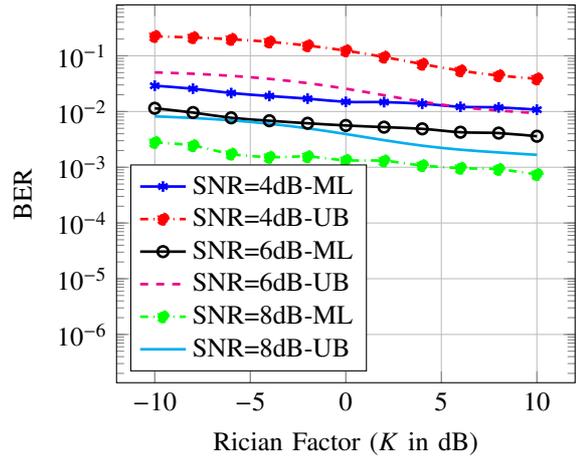

Fig. 6. S1: Comparison of the average BER and the theoretical upper bound (UB).

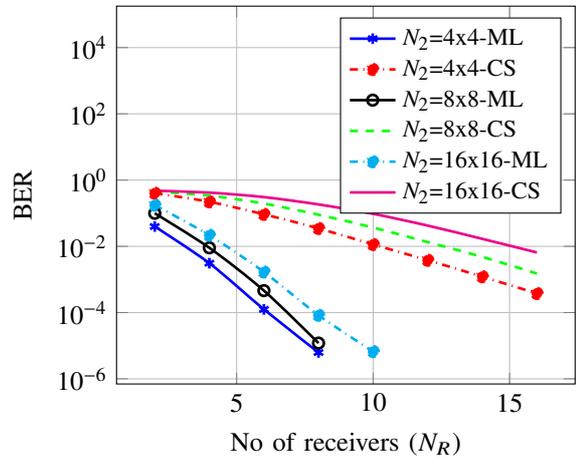

Fig. 7. S1: Effect of the number of receivers (N_R) on the BER.

number of elements in all three cases are kept the same. Therefore, for S3, where the optimization is to be carried out in an array, a 2×2 element array is considered to form a single RS. Hence, the effective dimension of IRS_2 in S3 is 4×4 , while it is 8×8 in the case of S1 and S2. Hence, the data rate will be lowest for S3, whereas it is the highest for S2, since there are more RSs in IRS_1 . The data rate for S1, S2 and S3 are 10, 14 and 8, respectively. In Fig. 8, the legends S3O1 and S3O2 represent the results of two optimization methods, i.e. the solution of (7) and that of (10), respectively. Both these schemes perform better than S1 and S2. This is because there is an increase in the received SNR due to optimization. In addition in S3, the modulating symbol is embedded in 4 elements, which gives an additional performance improvement. This makes the BER gap between the curves of S3 and the other schemes substantial. Observe that S3O1 performs marginally better than S3O2. This is because S3O2 maximizes the lower bound, whereas S3O1 operates on the exact function. Note that S3O1 performs almost similar to the solution of

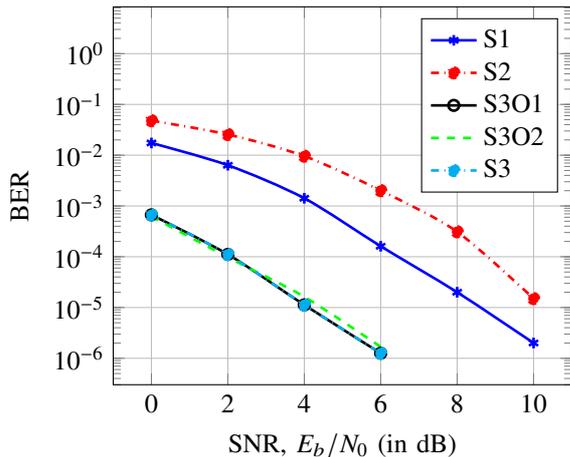

Fig. 8. Comparison of three different schemes.

the exact equation (4). The performance of $S2$ is approximately 2 dB worse than that of $S1$. There are two differences between these two schemes. In $S2$, the same QAM/PSK symbol is carried by more than one elements in IRS_2 . Hence, the probability of error in decoding the modulating symbol is reduced compared to $S1$. However, the information carried by the beam-index is higher in the case of $S2$, whose probability of decoding error will be higher than that of $S1$. The average BER reflects these two opposite effects.

Fig. 9 shows the effect of the number of RSs (N_T) in IRS_1 on the BER performance in $S3$ for different number of receivers (N_R) for CS detector. Similar to Fig. 7, this is also under Rayleigh channel condition. The average BER increases as N_T increases, which can be reduced by increasing the number of receivers. However, as N_T increases, the data rate increases. In this case, for the single RS case (which is equivalent to $S1$), the data rate is 10 bpcu , while it is 14, 23, 30 and 36 for $N_T = 2, 4, 6$ & 8, respectively. Finally, in Fig. 10, the effect of channel estimation errors is demonstrated. The true channel coefficients are corrupted by adding noise having a variance of σ_R^2 , which affects both the optimization as well as detection. The average BER is shown in the figure both with and without channel estimation. It can be seen that both $S1$ and $S2$ have approximately $2\text{--}3\text{ dB}$ performance degradation owing to the channel estimation error, whereas this gap is in excess of 4 dB for $S3$. This is because, in $S3$, the contaminated channel information is used both for optimization and detection.

VII. CONCLUSIONS

We proposed beam index modulation for millimeter wave communication exploiting the benefits of IRSs. The proposed scheme has three main advantages: 1) It achieves low-cost beamforming by using IRS for applying phase shifts, 2) it is capable of achieving reliable communication with the help of multiple IRSs in non-LOS scenarios, and 3) it sends additional in-

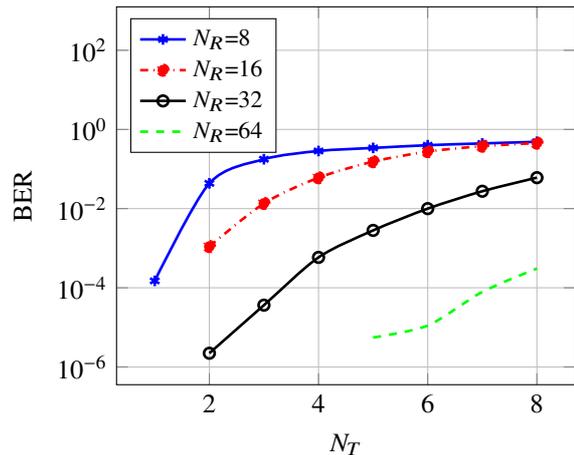

Fig. 9. $S2$: Effect of the number of reflecting surfaces in IRS_1 (N_T)

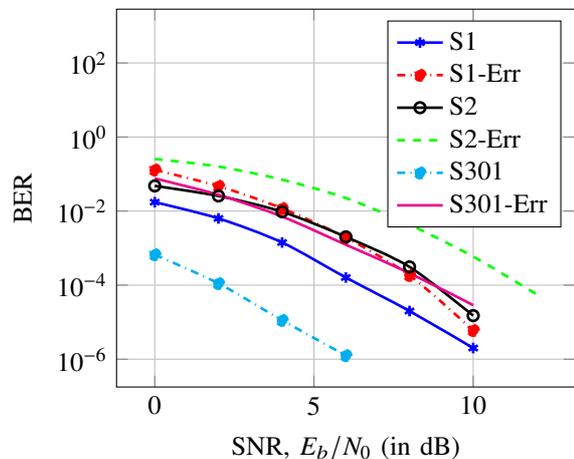

Fig. 10. Effect of channel estimation error.

formation using beam-index modulation without any additional cost. Furthermore, we developed the optimal ML detector and a low-complexity compressed sensing detector for the proposed schemes. An upper bound of the average BER of the optimal ML detector is also achieved. Finally, the performance of the proposed schemes was evaluated through extensive simulations.

APPENDIX A PROOF OF LEMMA 1

$$\begin{aligned} \|\mathbf{H}_Q \Theta_Q \mathbf{b}_{Q,s}\|^2 &= (\mathbf{b}_{Q,s})^H \Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q (\mathbf{b}_{Q,s}) \\ &= \text{Tr} \left\{ (\mathbf{b}_{Q,s})^H \Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q (\mathbf{b}_{Q,s}) \right\} \\ &= \text{Tr} \left\{ \Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q (\mathbf{b}_{Q,s}) (\mathbf{b}_{Q,s})^H \right\}. \end{aligned} \quad (21)$$

Note that $\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q$ and $(\mathbf{b}_{Q,s}) (\mathbf{b}_{Q,s})^H$ are positive definite matrices. Therefore applying [65, Theorem 2] on (21) results in (8). Now, since \mathbf{H}_Q is a random matrix and if $R \geq Q$, $\mathbf{H}_Q^H \mathbf{H}_Q$ will be a full-rank matrix with probability 1 and consequently $\lambda_{\min} \left(\Theta_Q^H \mathbf{H}_Q^H \mathbf{H}_Q \Theta_Q \right) > 0$.

APPENDIX B
PROOF OF THEOREM 1

Lemma 2 of Appendix C gives the conditional probability $\Pr\{r_j > r_k | \mathbf{A}\}$. Explicitly, the conditional probabilities are in the form of complementary error function (Q -functions). The distributions of the arguments of these Q -functions are derived in Lemma 3 in Appendix D. Therefore, the unconditional probabilities can be calculated by taking expectation of conditional probabilities (36) with respect to the corresponding distributions of their arguments in (43) and (44).

For $k = i$, the argument of the conditional probability is a Γ -distributed random variable with rate parameter $b = \frac{2\sigma_R^2}{(\Pi_p^i - \Pi_p^j)^H \Theta^H \Sigma_c \Theta (\Pi_p^i - \Pi_p^j)}$ and shape parameter $k = N_R$, i.e., $f_{\gamma_{ij}}(\gamma_{ij}) = \frac{1}{\Gamma(k)} b^k \gamma_{ij}^{k-1} e^{-b\gamma_{ij}}$. The unconditional probability in this case is

$$\Pr\{r_j > r_i\} = \int_0^\infty Q(\sqrt{\gamma_{ij}}) f_{\gamma_{ij}}(\gamma_{ij}) d\gamma_{ij}. \quad (22)$$

The closed-form expression for (22) given in [66, Eq. (A12)] can be applied to get (19). This proves the first part of the theorem.

For $k \neq i$, the probability is computed as follows. First we will consider the case of $q_R \neq 0$. By exploiting the relationship $Q(x) = 1 - Q(-x)$, the probability $\Pr\{r_j > r_k\}$ can be written as:

$$\begin{aligned} \Pr\{r_j > r_k\} &= \int_{-\infty}^\infty Q(\kappa) f_\kappa(\kappa) d\kappa \\ &= \int_{-\infty}^0 (1 - Q(-\kappa)) f_\kappa(\kappa) d\kappa + \int_0^\infty Q(\kappa) f_\kappa(\kappa) d\kappa \\ &= \int_0^\infty f_\kappa(-\kappa) d\kappa + \int_0^\infty Q(\kappa) (f_\kappa(\kappa) - f_\kappa(-\kappa)) d\kappa \\ &= \tilde{C} (I_1 + I_2), \end{aligned} \quad (23)$$

where $\tilde{C} = \frac{2\Gamma(2N_R)}{\Gamma(N_R)\sqrt{\pi\sigma_k^2}} \left(\frac{v-1}{2v}\right)^{N_R}$ is a constant term and

$$I_1 = \int_0^\infty e^{-\frac{2v-1}{2v\sigma_k^2} \kappa^2} D_{-2N_R} \left(\sqrt{\frac{2}{v\sigma_k^2}} \kappa \right) d\kappa, \quad (24)$$

while

$$\begin{aligned} I_2 &= \int_0^\infty Q(\kappa) e^{-\frac{2v-1}{2v\sigma_k^2} \kappa^2} \left[D_{-2N_R} \left(-\sqrt{\frac{2}{v\sigma_k^2}} \kappa \right) \right. \\ &\quad \left. - D_{-2N_R} \left(\sqrt{\frac{2}{v\sigma_k^2}} \kappa \right) \right] d\kappa. \end{aligned} \quad (25)$$

Note $D_{(\cdot)}(\cdot)$ is the parabolic cylinder function [67, pp. 45] and it can be written in terms Kummer's confluent

hypergeometric function ${}_1F_1(\cdot)$ as [68, pp. 39 (23)]

$$\begin{aligned} D_K(z) &= 2^{\frac{K}{2}} \sqrt{\pi} e^{-\frac{z^2}{4}} \left[\frac{1}{\Gamma\left(\frac{1-K}{2}\right)} {}_1F_1\left(-\frac{K}{2}; \frac{1}{2}; \frac{z^2}{2}\right) \right. \\ &\quad \left. - \frac{z}{\sqrt{2}\Gamma\left(-\frac{K}{2}\right)} {}_1F_1\left(\frac{1-K}{2}; \frac{3}{2}; \frac{z^2}{2}\right) \right]. \end{aligned} \quad (26)$$

Let us substitute $\kappa = +\sqrt{t}$ into (24) and expand $D_{-2N_R}(\cdot)$ using (26). Note that $d\kappa = \frac{1}{2\sqrt{t}} dt$. Therefore I_1 becomes:

$$\begin{aligned} I_1 &= \frac{\sqrt{\pi} 2^{-(N_R+1)}}{\Gamma\left(N_R + \frac{1}{2}\right)} \int_0^\infty t^{-\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(N_R; \frac{1}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &\quad - \frac{2^{-(N_R+1)}}{\Gamma(N_R)} \sqrt{\frac{\pi}{v\sigma_k^2}} \int_0^\infty e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right) dt. \end{aligned} \quad (27)$$

Now, the difference in (25) is formulated as:

$$\begin{aligned} \Delta &= D_{-2N_R} \left(-\sqrt{\frac{2t}{v\sigma_k^2}} \right) - D_{-2N_R} \left(\sqrt{\frac{2t}{v\sigma_k^2}} \right) \\ &= \frac{2e^{-\frac{t}{2v\sigma_k^2}} 2^{-N_R}}{\Gamma(N_R)} \sqrt{\frac{\pi t}{v\sigma_k^2}} {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right). \end{aligned} \quad (28)$$

In order to evaluate I_2 , first we express the Q -function in terms of the complimentary error function as $Q(x) = \frac{1}{2} \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)$ [69, pp. 40], and then subsequently it is expressed in terms of the hypergeometric function as [70]:

$$Q(x) = \frac{1}{2} - \frac{x}{\sqrt{2\pi}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -\frac{x^2}{2}\right). \quad (29)$$

Upon substituting (28) and (29) into (25), I_2 becomes:

$$\begin{aligned} I_2 &= \frac{2^{-(N_R+1)}}{\Gamma(N_R)} \sqrt{\frac{\pi}{v\sigma_k^2}} \int_0^\infty e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &\quad - \frac{2^{-N_R}}{\Gamma(N_R)} \sqrt{\frac{1}{2v\sigma_k^2}} \int_0^\infty t^{\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -\frac{t}{2}\right) \\ &\quad {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right) dt. \end{aligned} \quad (30)$$

Note that the second term of the RHS in (27) and the first term of RHS in (30) will get cancelled. Hence $\Pr\{r_j > r_k\}$ will become:

$$\begin{aligned} \Pr\{r_j > r_k\} &= C_1 \int_0^\infty t^{-\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(N_R; \frac{1}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &\quad - C_2 \int_0^\infty t^{\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -\frac{t}{2}\right) {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &= C_1 I_3 + C_2 I_4, \end{aligned} \quad (31)$$

where $C_1 = \frac{1}{2\sqrt{\pi\sigma_k^2}} \left(\frac{v-1}{v}\right)^{N_R}$ and $C_2 = \frac{1}{\pi\sigma_k^2 \sqrt{2v}} \frac{\Gamma(N_R + \frac{1}{2})}{\Gamma(N_R)} \left(\frac{v-1}{v}\right)^{N_R}$. Note that we have exploited the relationship $\Gamma(x)\Gamma\left(x + \frac{1}{2}\right) = \frac{\sqrt{\pi}}{2^{2x-1}} \Gamma(2x)$

[71, Theorem 6] for reducing C_1 and C_2 . Now, I_3 is expressed using equation [72, pp. 822, equation(7.621(4))] and it is given below:

$$\begin{aligned} I_3 &= \int_0^\infty t^{-\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(N_R; \frac{1}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &= \Gamma\left(\frac{1}{2}\right) \sqrt{\sigma_k^2} {}_2F_1\left(N_R, \frac{1}{2}; \frac{1}{2}; \frac{1}{v}\right) \\ &= \sqrt{\pi\sigma_k^2} \left(1 - \frac{1}{v}\right)^{-N_R}, \end{aligned} \quad (32)$$

where ${}_2F_1(a, b; c; z)$ is Gauss' Hypergeometric function [67, pp. 42]. Observe that ${}_2F_1(a, b; b; z) = {}_1F_0(a; z) = (1-z)^{-a}$ [73, A1]. In order to evaluate the integral I_4 , we make the substitution $z = \frac{t}{v\sigma_k^2}$ and use [72, pp. 823, equation (7.622(1))] and the integral becomes:

$$\begin{aligned} I_4 &= \int_0^\infty t^{\frac{1}{2}} e^{-\frac{t}{\sigma_k^2}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -\frac{t}{\sigma_k^2}\right) {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; \frac{t}{v\sigma_k^2}\right) dt \\ &= (v\sigma_k^2)^{\frac{3}{2}} \int_0^\infty z^{\frac{1}{2}} e^{-vz} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -\frac{v\sigma_k^2 z}{\sigma_k^2}\right) {}_1F_1\left(N_R + \frac{1}{2}; \frac{3}{2}; z\right) dz \\ &= \sqrt{\frac{\pi(\sigma_k^2)^3}{2(2+\sigma_k^2)}} {}_2F_1\left(N_R + \frac{1}{2}; \frac{1}{2}; \frac{3}{2}; -\frac{\sigma_k^2}{(v-1)(2+\sigma_k^2)}\right) \left(\frac{v-1}{v}\right)^{-(N_R+\frac{1}{2})}. \end{aligned} \quad (33)$$

Now we apply the transformations ${}_2F_1(a, b; c; z) = (1-z)^{-b} {}_2F_1(c-a, b; c; \frac{z}{z-1})$ [74] and ${}_2F_1(a, b; b+1; z) = bz^{-b} \mathcal{B}_z(b, 1-a)$ [75], when (33) becomes:

$$I_4 = \frac{\sigma_k^2}{2} \sqrt{\frac{\pi v}{2}} \left(\frac{v-1}{v}\right)^{-N_R} \mathcal{B}_{\frac{\sigma_k^2}{2(v-1)+v\sigma_k^2}}\left(\frac{1}{2}, N_R\right), \quad (34)$$

where $\mathcal{B}_z(a, b) = \mathcal{B}(a, b)z^a \sum_{k=0}^{b-1} \frac{(a)_k}{k!} (1-z)^k$ is the incomplete Beta function [76] with $\mathcal{B}(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$ being the Beta function and $(a)_k$ is the Pochhammer symbol. Finally upon substituting (32) and (34) into (31), we arrive at:

$$\begin{aligned} \Pr\{r_j > r_k\} &= \frac{1}{2} \\ &- \frac{1}{4} \sqrt{\frac{\sigma_k^2}{2(v-1)+v\sigma_k^2}} \sum_{n=0}^{N_R-1} \frac{\left(\frac{1}{2}\right)_n}{n!} \left(1 - \frac{\sigma_k^2}{2(v-1)+v\sigma_k^2}\right)^n. \end{aligned} \quad (35)$$

Now substituting for v and the Pochhammer symbol $(a)_n = \frac{\Gamma(n+a)}{\Gamma(a)}$ [77] will give the second term in the RHS of (20).

Finally, when $q_R = 0$, the distribution of κ is zero mean Gaussian. Hence, in this case I_2 in (23) will be zero, while $I_1 = \frac{1}{2}$ and the constant $\tilde{C} = 1$, which completes the proof.

APPENDIX C

CONDITIONAL PROBABILITY $\Pr\{r_j > r_k|\mathbf{A}\}$

Lemma 2. Let $\Pi_{\mathbf{p}}^i$ be the transmitted signal. Then, we have

$$\Pr\{r_j > r_k|\mathbf{A}\} = \begin{cases} Q\left(\sqrt{\gamma_{ij}}\right), & \text{if } k = i \\ Q(\kappa), & \text{otherwise} \end{cases}, \quad (36)$$

where $Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-\frac{t^2}{2}} dt$ is the complementary error function and

$$\gamma_{kj} = \frac{1}{2} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j\right)^H \mathbf{A}^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j\right), \quad (37)$$

and

$$\kappa = \frac{\gamma_{ik} - \gamma_{ij}}{\sqrt{\gamma_{kj}}}. \quad (38)$$

Proof. First the conditional probability $\Pr\{r_j > r_k|\mathbf{A}\}$ is estimated for $k \neq i$ when $\Pi_{\mathbf{p}}^i$ is transmitted as follows. The event $r_j > r_k$ is

$$\mathcal{R}e\left\{\left(\mathbf{y} - \frac{1}{2}\mathbf{A}\Pi_{\mathbf{p}}^k\right)^H \Sigma^{-1} \mathbf{A}\Pi_{\mathbf{p}}^k\right\} < \mathcal{R}e\left\{\left(\mathbf{y} - \frac{1}{2}\mathbf{A}\Pi_{\mathbf{p}}^j\right)^H \Sigma^{-1} \mathbf{A}\Pi_{\mathbf{p}}^j\right\}. \quad (39)$$

Using (12), (39) can be written as:

$$\begin{aligned} \mathcal{R}e\left\{\left(\mathbf{w} + \mathbf{A}\Pi_{\mathbf{p}}^i\right)^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j\right)\right\} \\ < \mathcal{R}e\left\{-\frac{1}{2} \left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k\right)^H \mathbf{A}^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k\right)\right\}. \end{aligned} \quad (40)$$

Hence, $\Pr\{r_j > r_k|\mathbf{A}\} = \Pr\{\eta < g_{jk}|\mathbf{A}\}$, where $\eta = \mathcal{R}e\left\{\left(\mathbf{w} + \mathbf{A}\Pi_{\mathbf{p}}^i\right)^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j\right)\right\}$ and g_{jk} is the RHS of (40). Finally, note that $\eta \sim \mathcal{N}(\mu_{jk}, \gamma_{jk})$, where $\mu_{jk} = \mathcal{R}e\left\{\left(\Pi_{\mathbf{p}}^i\right)^H \mathbf{A}^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j\right)\right\}$ and γ_{jk} is defined in (37). Now, let us make a substitution $\tilde{\eta} = \frac{\eta - \mu_{jk}}{\sqrt{\gamma_{jk}}}$. Clearly, $\tilde{\eta}$ is a standard normal random variable and hence the probability in (37) can be written in the form of the Q -function as:

$$\Pr\{r_j > r_k|\mathbf{A}\} = \Pr\left\{\tilde{\eta} < -\frac{s_{jk}}{\sqrt{\gamma_{jk}}}\right\} = Q\left(\frac{s_{jk}}{\sqrt{\gamma_{jk}}}\right), \quad (41)$$

where we have

$$\begin{aligned} s_{jk} &= -(g_{jk} - \mu_{jk}) \\ &= \mathcal{R}e\left\{\frac{1}{2} \left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k\right)^H \mathbf{A}^H \Sigma^{-1} \mathbf{A} \left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k - 2\Pi_{\mathbf{p}}^i\right)\right\} \\ &= \mathcal{R}e\left\{\frac{1}{2} \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i\right) - \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i\right)\right)^H \right. \\ &\quad \left. \mathbf{A}^H \Sigma^{-1} \mathbf{A} \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i\right) + \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i\right)\right)\right\} \\ &= \gamma_{ij} - \gamma_{ik}. \end{aligned} \quad (42)$$

When $k = i$, we have $\gamma_{ik} = 0$ and therefore (41) becomes $\Pr\{r_j > r_i|\mathbf{A}\} = Q\left(\sqrt{\gamma_{ij}}\right)$. This completes the proof. \square

APPENDIX D

DISTRIBUTION OF γ_{mn} AND κ

Lemma 3. Under the assumptions of Theorem 1,

- 1) The random variable γ_{kj} defined in (37) is a Γ -distributed random variable, i.e.,

$$\gamma_{kj} \sim \Gamma \left(N_R, \frac{2\sigma_R^2}{\left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j \right)^H \Theta^H \Sigma_c \Theta \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j \right)} \right). \quad (43)$$

- 2) When $q_R \neq 0$, the distribution of the random variable κ defined in (38) is

$$f_{\kappa}(\kappa) = \frac{2\Gamma(2N_R) e^{-\frac{2v-1}{2v\sigma_{\tilde{\kappa}}^2} \kappa^2}}{\Gamma(N_R) \sqrt{\pi\sigma_{\tilde{\kappa}}^2}} \left(\frac{v-1}{2v} \right)^{N_R} D_{-2N_R} \left(-\sqrt{\frac{2}{v\sigma_{\tilde{\kappa}}^2}} \kappa \right), \quad (44)$$

where $D_K(\cdot)$ is the Parabolic cylinder function [67, pp. 45] and the parameters are defined in Theorem 1.

- 3) For $q_R = 0$, $\kappa \sim \mathcal{N}(0, \frac{\sigma_{\tilde{\kappa}}^2}{2})$, where $\sigma_{\tilde{\kappa}}^2$ is defined in (54)

Proof. When we have $\sigma_2^2 \ll \sigma_R^2$, γ_{kj} in (37) can be approximated as:

$$\gamma_{kj} \approx \frac{1}{2\sigma_R^2} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j \right)^H \mathbf{A}^H \mathbf{A} \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^j \right). \quad (45)$$

Recall that $\mathbf{A} = \mathbf{H}\Theta$. Under the assumptions of Theorem 1, $\mathbf{H}^H \mathbf{H}$ obeys a non-central complex Wishart distribution, i.e., $\mathbf{H}^H \mathbf{H} \sim \mathcal{W}(N_R, \tilde{\mathbf{H}}, \tilde{\Sigma}_c)$. This can be approximated as a central complex Wishart distribution having the covariance matrix of $\Sigma_c = \tilde{\Sigma}_c + \frac{1}{N_R} \tilde{\mathbf{H}}^H \tilde{\mathbf{H}}$ [78]¹. If we use this approximation, it can be assumed that each entry of \mathbf{H} is distributed according to $\mathcal{CN}(0, \Sigma_c)$. Hence, the random variable $\mathbf{z} = \frac{1}{\sqrt{2\sigma_R^2}} \mathbf{A} \left(\Pi_{\mathbf{p}}^i - \Pi_{\mathbf{p}}^j \right)$ is distributed according to $\mathcal{CN} \left(0, \frac{1}{2\sigma_R^2} \left(\Pi_{\mathbf{p}}^i - \Pi_{\mathbf{p}}^j \right)^H \Theta^H \Sigma_c \Theta \left(\Pi_{\mathbf{p}}^i - \Pi_{\mathbf{p}}^j \right) \mathbf{I} \right)$. Hence, $\gamma = \mathbf{z}^H \mathbf{z}$ is a Gamma distributed variable having the distribution function of (43). This proves the first part of the Lemma.

The rest of the Lemma is proved as follows. Define $\mathbf{z}_1 = \frac{1}{\sqrt{2\sigma_R^2}} \mathbf{A} \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i \right) - \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i \right) \right)$ and $\mathbf{z}_2 = \frac{1}{\sqrt{2\sigma_R^2}} \mathbf{A} \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i \right) + \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i \right) \right)$. Similar to the case of first part of this Lemma, the distributions of \mathbf{z}_1 and \mathbf{z}_2 can be approximated as $\mathbf{z}_1 \sim \mathcal{CN}(0, \sigma_{z_1}^2 \mathbf{I})$ and $\mathbf{z}_2 \sim \mathcal{CN}(0, \sigma_{z_2}^2 \mathbf{I})$, where

$$\sigma_{z_1}^2 = \frac{\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k \right)^H \Theta^H \Sigma_c \Theta \left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k \right)}{2\sigma_R^2}, \quad (46)$$

and

$$\sigma_{z_2}^2 = \frac{\left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k - 2\Pi_{\mathbf{p}}^i \right)^H \Theta^H \Sigma_c \Theta \left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k - 2\Pi_{\mathbf{p}}^i \right)}{2\sigma_R^2}. \quad (47)$$

¹For Rayleigh channel, $\mathbf{H}^H \mathbf{H}$ exactly follows the central complex Wishart distribution associated with $\Sigma_c = \mathbf{I}$

Also note that $\mathbb{E} \{ \mathbf{z}_1 \mathbf{z}_2^H \} = q \mathbf{I}$ and $\mathbb{E} \{ \mathbf{z}_2 \mathbf{z}_1^H \} = q^H \mathbf{I}$, where

$$q = \frac{1}{2\sigma_R^2} \text{Tr} \left\{ \left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k \right) \left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k - 2\Pi_{\mathbf{p}}^i \right)^H \Theta^H \Sigma_c \Theta \right\} \\ = \frac{\left(\Pi_{\mathbf{p}}^j + \Pi_{\mathbf{p}}^k - 2\Pi_{\mathbf{p}}^i \right)^H \Theta^H \Sigma_c \Theta \left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^k \right)}{2\sigma_R^2}. \quad (48)$$

Now we can rewrite γ_{kj} in (45) as:

$$\gamma_{kj} \approx \frac{1}{2\sigma_R^2} \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i \right) - \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i \right) \right)^H \mathbf{A}^H \mathbf{A} \\ \left(\left(\Pi_{\mathbf{p}}^j - \Pi_{\mathbf{p}}^i \right) - \left(\Pi_{\mathbf{p}}^k - \Pi_{\mathbf{p}}^i \right) \right) \\ = \|\mathbf{z}_1\|^2. \quad (49)$$

Similarly $\kappa \approx \mathcal{R}e \left\{ \frac{\mathbf{z}_1^H \mathbf{z}_2}{\|\mathbf{z}_1\|} \right\}$. First we derive the distribution of κ given \mathbf{z}_1 . Note that \mathbf{z}_1 and \mathbf{z}_2 are complex Gaussian distributed random vectors. Hence, the distribution $f_{\kappa|\mathbf{z}_1}(\kappa|\mathbf{z}_1)$ is Gaussian. Let $\tilde{\kappa} = \frac{\mathbf{z}_1^H \mathbf{z}_2}{\|\mathbf{z}_1\|}$. Therefore, using [79, prop. 3.13], we have $\mu_{\tilde{\kappa}} = \mathbb{E} \{ \tilde{\kappa} | \mathbf{z}_1 = \tilde{\mathbf{z}} \} = \frac{q^H}{\sigma_{z_1}^2} \|\tilde{\mathbf{z}}\|$. Note that $\kappa = \mathcal{R}e \{ \tilde{\kappa} \}$ and hence $\mathbb{E} \{ \kappa | \mathbf{z}_1 = \tilde{\mathbf{z}} \} = \mathcal{R}e \{ \mu_{\tilde{\kappa}} \} = \frac{q_R}{\sigma_{z_1}^2} \|\tilde{\mathbf{z}}\|$, where $q_R = \mathcal{R}e \{ q \}$. In order to compute variance of the κ given \mathbf{z}_1 , let us expand κ as:

$$\kappa = \mathcal{R}e \left\{ \frac{\mathbf{z}_1^H \mathbf{z}_2}{\|\mathbf{z}_1\|} \right\} = \frac{\mathcal{R}e \{ \mathbf{z}_1 \}^T \mathcal{R}e \{ \mathbf{z}_2 \}}{\|\mathbf{z}_1\|} + \frac{\mathcal{I}m \{ \mathbf{z}_1 \}^T \mathcal{I}m \{ \mathbf{z}_2 \}}{\|\mathbf{z}_1\|}. \quad (50)$$

Let $u_1 = \frac{\mathcal{R}e \{ \mathbf{z}_1 \}^T \mathcal{R}e \{ \mathbf{z}_2 \}}{\|\mathbf{z}_1\|}$ and $u_2 = \frac{\mathcal{I}m \{ \mathbf{z}_1 \}^T \mathcal{I}m \{ \mathbf{z}_2 \}}{\|\mathbf{z}_1\|}$. Hence,

$$\text{var}(\kappa | \mathbf{z}_1 = \tilde{\mathbf{z}}) = \text{var}(u_1 | \mathbf{z}_1 = \tilde{\mathbf{z}}) + \text{var}(u_2 | \mathbf{z}_1 = \tilde{\mathbf{z}}) \\ + \text{Cov}(u_1, u_2 | \mathbf{z}_1 = \tilde{\mathbf{z}}) + \text{Cov}(u_2, u_1 | \mathbf{z}_1 = \tilde{\mathbf{z}}). \quad (51)$$

Using [79, prop. 3.13], it can be shown that:

$$\text{var}(u_1 | \mathbf{z}_1 = \tilde{\mathbf{z}}) = \frac{\mathcal{R}e \{ \tilde{\mathbf{z}} \}^T \text{Cov} \{ \mathcal{R}e \{ \mathbf{z}_2 \} | \mathbf{z}_1 = \tilde{\mathbf{z}} \} \mathcal{R}e \{ \tilde{\mathbf{z}} \}}{\|\tilde{\mathbf{z}}\|^2} \\ = \frac{\mathcal{R}e \{ \tilde{\mathbf{z}} \}^2}{\|\tilde{\mathbf{z}}\|^2} \frac{1}{2} \left(\sigma_{z_2}^2 - \frac{\|q\|^2}{2\sigma_{z_1}^2} \right). \quad (52)$$

Similarly, $\text{var}(u_2 | \mathbf{z}_1 = \tilde{\mathbf{z}}) = \frac{\mathcal{I}m \{ \tilde{\mathbf{z}} \}^2}{\|\tilde{\mathbf{z}}\|^2} \frac{1}{2} \left(\sigma_{z_2}^2 - \frac{\|q\|^2}{2\sigma_{z_1}^2} \right)$ and

$$\text{Cov}(u_1, u_2 | \mathbf{z}_1 = \tilde{\mathbf{z}}) = -\text{Cov}(u_2, u_1 | \mathbf{z}_1 = \tilde{\mathbf{z}}) \\ = -j \frac{\|q\|^2}{4\sigma_{z_1}^2} \frac{\mathcal{R}e \{ \mathbf{z}_1 \}^T \mathcal{I}m \{ \mathbf{z}_1 \}}{\|\mathbf{z}_1\|^2}. \quad (53)$$

Therefore, $\text{var}(\kappa | \mathbf{z}_1 = \tilde{\mathbf{z}}) = \frac{1}{2} \left(\sigma_{z_2}^2 - \frac{\|q\|^2}{2\sigma_{z_1}^2} \right)$. Hence, $\kappa | \mathbf{z}_1 \sim \mathcal{N} \left(\frac{q_R}{\sigma_{z_1}^2} \|\tilde{\mathbf{z}}\|, \frac{\sigma_{\tilde{\kappa}}^2}{2} \right)$, where

$$\sigma_{\tilde{\kappa}}^2 = \left(\sigma_{z_2}^2 - \frac{\|q\|^2}{2\sigma_{z_1}^2} \right). \quad (54)$$

If $q_R = 0$, $f_{\kappa|z_1}$ is independent of z_1 and hence the unconditional distribution of κ is the same as the conditional distribution, i.e., $\kappa \sim \mathcal{N}(0, \frac{\sigma_\kappa^2}{2})$.

When $q_R \neq 0$, the unconditional distribution can be obtained by eliminating the conditioning with respect to the distribution of $\|\bar{z}\|$, which is Nakagami distributed *Nakagami* $(N_R, N_R \sigma_{z_1}^2)$, since $\|\bar{z}\|^2 \sim \Gamma(N_R, \frac{1}{\sigma_{z_1}^2})$. Explicitly, $f_{\bar{z}}(\bar{z}) = \frac{2\bar{z}^{2N_R-1} e^{-\frac{\bar{z}^2}{\sigma_{z_1}^2}}}{\Gamma(N_R)(\sigma_{z_1}^2)^{N_R}}$ [80], where $\bar{z} = \|\bar{z}\|$. Hence, the unconditional distribution of κ is:

$$f_{\kappa}(\kappa) = \frac{2 \int_0^\infty e^{-g(\kappa, \bar{z})} \bar{z}^{2N_R-1} d\bar{z}}{(\sigma_{z_1}^2)^{N_R} \Gamma(N_R) \sqrt{\pi \sigma_\kappa^2}}, \quad (55)$$

where

$$\begin{aligned} g(\kappa, \bar{z}) &= \frac{\left(\kappa - \frac{q_R}{\sigma_{z_1}^2} \bar{z}\right)^2}{\sigma_\kappa^2} + \frac{\bar{z}^2}{\sigma_{z_1}^2} \\ &= \frac{\kappa^2}{\sigma_\kappa^2} + \frac{q_R^2 + \sigma_{z_1}^2 \sigma_\kappa^2}{(\sigma_{z_1}^2)^2 \sigma_\kappa^2} \bar{z}^2 - \frac{2q_R \kappa}{\sigma_{z_1}^2 \sigma_\kappa^2} \bar{z}. \end{aligned} \quad (56)$$

Now using [72, 3.462(1)], we arrive at:

$$\begin{aligned} I_{\kappa} &= \int_0^\infty e^{-g(\kappa, \bar{z})} \bar{z}^{2N_R-1} d\bar{z} \\ &= e^{-\frac{\kappa^2}{\sigma_\kappa^2}} \int_0^\infty e^{-\frac{q_R^2 + \sigma_{z_1}^2 \sigma_\kappa^2}{(\sigma_{z_1}^2)^2 \sigma_\kappa^2} \bar{z}^2 + \frac{2q_R \kappa}{\sigma_{z_1}^2 \sigma_\kappa^2} \bar{z}} \bar{z}^{2N_R-1} d\bar{z} \\ &= e^{-\frac{\kappa^2}{\sigma_\kappa^2}} \left(\frac{\sigma_{z_1}^2 (v-1)}{2v}\right)^{N_R} \Gamma(2N_R) e^{\frac{\kappa^2}{2\sigma_\kappa^2 v}} D_{-2N_R} \left(-\sqrt{\frac{2}{\sigma_\kappa^2 v}} \kappa\right), \end{aligned} \quad (57)$$

where $v = 1 + \frac{\sigma_\kappa^2 \sigma_{z_1}^2}{q_R^2}$. Finally, substituting (57) into (55) will give (44). \square
