Study on the efficient PV/TE characteristics of the self-assembled thin films based on bismuth telluride/cadmium telluride

Vivekanandan Raman,^a Dinah Punnoose,^a Pari Baraneedharan,^b Sunkara Srinivasa Rao,^a Chandu V. V. M. Gopi,^a Venkatesh S,^c S Brahadeeswaran^d and Hee-Je Kim^{*a}

Solar radiation has a spectral distribution ranging from short wavelengths (200–800 nm, visible part) to long wavelengths (800–3000 nm, heat part). Cadmium telluride and bismuth telluride are well known photovoltaic (PV) and thermoelectric (TE) materials, respectively. CdTe converts light energy into electricity and Bi₂Te₃ converts heat into electricity. To effectively use the entire solar spectrum for energy conversion, a new type of solar cell based on a Bi₂Te₃/CdTe composite in a core/shell structure was designed and prepared using a wet chemical method. X-ray diffraction and high-resolution transmission electron microscopy confirmed the formation of Bi₂Te₃/CdTe in a core/shell structure with high crystallinity. Bi₂Te₃ nanoparticles function as built-in nanoscale electron generators to convert heat into electricity and CdTe functions as a photovoltaic cell. The efficiency of the thin film solar cell device was found to be 2.5% at room temperature and 4.8% when exposed to sunlight. The combined PV and TE modules resulted in an overall power conversion efficiency of 4.8%.

1. Introduction

Solar energy is the cleanest and the most abundant renewable energy source available. CdTe, CuIn(Ga)Se₂, and c-Si are advanced materials that are used as absorber materials in solar cells.¹ Although these materials have high efficiency, the lack of abundance, high toxicity levels, and high production costs are problems that have prompted researchers to search for new materials and/or newer and easier synthesis routes. Therefore, continuous efforts are being made to find new, cost-effective photovoltaic materials with good conversion efficiency. Solar radiation has a spectral distribution from the short wavelength range, 200–800 nm (light part), to the long wavelength range, 800–3000 nm (heat part). Better control of light scattering and electronic transport through a semiconductor is crucial for improving the solar efficiency. Photovoltaic cells (PV), such as CdTe, can only convert the short wavelengths of solar energy into electricity and the remaining long wavelength solar radiation is waste heat. Thermoelectric materials (TE), such as Bi₂Te₃, convert the waste heat into electricity. Bi₂Te₃ has a high

Seebeck coefficient and can generate electricity, even at room temperature.² Considerable efforts have been made to combine both PV and TE technologies to maximally utilize the entire solar spectrum. These hybrid technologies that combine the modules of PV and TE cannot solve the problems of solar energy synergy utilization at the material level because the functions of PV and TE modules are independent of each other. On the other hand, it will be beneficial if both the PV and TE functions can be achieved in a single material. If this single material can be prepared in a nanostructure, it will be more efficient. Nanoparticles of CdTe have good photoluminescence properties and have been used in the production of solar cells. CdTe nanoparticles are prepared *via* aqueous and non-aqueous synthesis routes. Compared to non-aqueous synthesis, aqueous synthesis is more reproducible, cheaper, and less toxic. In addition, the prepared samples are more water-soluble and bio-compatible.³ To prepare nanorods, a seed-mediated growth technique was performed, in which the precursor was added dropwise and the capping agent assisted in the growth of nanorods.^{4,5} This study reports the integration of photovoltaic CdTe and thermoelectric Bi₂Te₃ materials into a single photoelectrode in the form of a core/shell nanostructure. Interestingly, this material showed a conversion efficiency of 4.8% when exposed to sunlight.

Core/shell nanorods have been produced by a layer-by-layer self-assembly method. This is an effective technique for the construction of well-defined nanostructures. Hengguo Wang *et al.* reported that the LBL technique is facile and relatively controllable and they confirmed the incorporation of Fe₃O₄ and

quantum dots (QDs) into a single structure. The shell produced by this method is meant to be a functional hybrid nanoshell.^{6–9} The alternating adsorption of oppositely charged materials gives rise to a layer-by-layer (LBL) self-assembly deposition method, through which hydrogen-bonding interactions and electrostatic forces hold the nanostructures assembly together.^{10–12} The aim of developing Bi₂Te₃/CdTe core shell nanorods is to harvest electricity from both thermal energy and light energy produced by the sun. Jie Yang *et al.* proposed that self-assembled Bi₂Te₃/CdTe nanosheets showed an increase in the thermoelectric performance of Bi₂Te₃ due to the addition of CdTe, thus reaching a Seebeck coefficient of $-182.2 \mu\text{V K}^{-1}$ at 300 K, which is slightly higher than that of the bulk Bi₂Te₃ sample, $-180.0 \mu\text{V K}^{-1}$. This clearly shows that CdTe will also enhance the thermoelectric performance of Bi₂Te₃. Solar cells based on nanoparticles have higher solar efficiency because of their large surface area.¹³ Therefore, the increase in the surface area of planar nanorod carpets has been proposed to enhance solar light harvesting.^{14–16}

2. Experimental section

2.1 Materials

All chemicals, such as bismuth(III) nitrate pentahydrate (Bi(NO₃)₃·5H₂O), tellurium powder (Te), potassium hydroxide (KOH), polyvinyl alcohol (PVA), cadmium sulphate (CdSO₄), and sodium borohydride (NaBH₄), were purchased from Aldrich and used without further purification.

2.2 Synthesis of Bi₂Te₃/CdTe core shell thin film nanostructures

The front conductor influences the conductivity and plays a large role in the performance of a solar cell. An increase in the carrier mobility in the conductive FTO transparent conducting oxide layer provides lower absorptivity and lower resistivity.¹⁷ A FTO is properly cleaned to avoid weak adhesion, whereas a coating of CdS is deposited on the surface of the FTO. Acid exposure of the FTO will compromise the uniform deposition of CdS and affect the performance of the solar cell.¹⁸ CdS has high band width (2.4 eV) and acts as a windows layer for the cells, which plays a vital role in observing sunlight. In a clean FTO glass substrate, a three layer coating was deposited. The FTO substrate was masked and a 50–100 nm CdS layer was coated by thermal vapor deposition and annealed at 250 °C for 10 minutes. The CdS coating thickness affects the performance of the solar cell. The CdS should be thick enough because interdiffusion is promoted by the CdCl₂ washing at the end of the deposition. The interdiffusion usually takes place without CdCl₂. It has negative effects on cell operation. When the interdiffusion is strong enough, the light current is decreased. It has been claimed that a narrow interdiffusion of less than 100 nm between CdS and CdTe allows the smoother transition between both lattices, which should relax the surface states. When the thickness increases, the photo current decreases and absorption occurs.¹⁹ During the deposition of Bi₂Te₃/CdTe, interdiffusion between CdTe and CdS occurred. Moreover, CdS

should be thick enough to not to be fully consumed by CdTe.²⁰ Bi₂Te₃/CdTe core/shell nanorods were prepared by a wet chemical method. Bismuth(III) nitrate pentahydrate (0.04 mol) was placed in 10 mL of double-distilled water (DDW). Tellurium (0.06 mol) in 10 mL of DDW was mixed with bismuth nitrate solution and stirred. Subsequently, 0.5 mol of KOH was added to the abovementioned solution after 5 min. The CdS-coated FTO substrate was then immersed in the prepared solution. About 0.04 mol of the reducing agent, NaBH₄, was added dropwise to reduce the bismuth nitrate and tellurium to bismuth telluride nanoparticles.²¹ The reducing agent is oxidized because it loses electrons in the redox reaction. The first step involves the reduction of Bi(NO₃)₃·5H₂O and tellurium. When H₂O is added to Bi(NO₃)₃·5H₂O, salt separates into Bi³⁺ and 6NO⁻ ions, whereas in the case of Te powder, Te changes into Te²⁻. When NaBH₄ is added, these ions form clusters. In the second stage, the clusters coalesce to produce small particles with radius of 20–50 nm. This is followed by a metastable state, where the particles maintain the constant size for around 5–10 min. After 10–20 min, the last coalescence phase takes place to generate final Bi₂Te₃ nanoparticles about the size of 150–250 nm.

When NaBH₄ is added followed by stirring, nanorods of Bi₂Te₃ are formed *via* a self-assembly mechanism. Herein, in the self-assembly mechanism, at the critical concentration, the molecules start to interact with each other resulting in the nucleation of crystals. Using hydrogen bonding and electrostatic or ionic forces, Bi₂Te₃ clusters with itself to form nanorods. When PVA is added, it bonds to Bi₂Te₃. PVA plays a critical role in bonding Bi₂Te₃ and CdTe. PVA attracts the CdTe nanoclusters due to hydrogen bonding and forms core/shell nanorods, as shown in Fig. 1. A 0.1 g sample of polyvinyl alcohol (PVA) was added to the Bi₂Te₃ solution under stirring to form bonds with the Bi₂Te₃ nanoparticles. After 30 min of heating at 70 °C, the polymer PVA transformed the Bi₂Te₃ nanoparticles into nanorods, and the solution turned black and coated the CdS substrate. Cadmium sulfate and tellurium were then mixed in 20 mL of DDW with 0.04 and 0.06 molarity, respectively, and stirred well for 20 min. The solution was then poured into the Bi₂Te₃ nanorods solution, where CdTe forms a shell over Bi₂Te₃. The polymer plays a crucial role in reducing CdTe to nanoparticles and attaching over Bi₂Te₃. This mixture was kept at 70 °C and stirred well for 30 min. CdTe was coated over Bi₂Te₃ and the substrate was washed with CdCl₂ and distilled water, and then dried and annealed at 400 °C for 4 h. This procedure was followed to prepare different concentrations of bismuth telluride with

Fig. 1 Self-assembly of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ with the help of a PVA polymer.

cadmium telluride at ratios of 1 : 3, 1 : 1, and 3 : 1. Annealing at high temperatures encourages Cds/CdTe interdiffusion during growth, larger grain size, and generally provides a higher V_{oc} .²² This $\text{Bi}_2\text{Te}_3/\text{CdTe}$ will act as a p-type semiconducting layer, whereas CdS will act as an n-type semiconducting layer. Therefore, these two layers form a p-n junction. The back contact was coated with gold to reduce the resistance and increase the performance. A Cu wire was separately attached to the FTO and gold contact to complete the circuit.²⁰

2.3 Characterization

The phase identification of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, and $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ was investigated using X-ray diffraction (XRD; Bruker D8-Advance) with a Cu-K_α radiation ($\lambda = 1.540 \text{ \AA}$) source operated at 40 kV and 30 mA in the range of $10\text{--}60^\circ$. The morphology of the sample was examined using high resolution transmission electron microscopy (HRTEM; Jem 2011, Jeol cop.) with a CCD $4k \times 4k$ camera (Ultra Scan 400SP, Gatan cop.) at the Busan KBSI. X. The constituents and morphological changes of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, and $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ and the elemental compositions of the samples were examined using a field emission scanning electron microscope (FE-SEM, SU-70, Hitachi) operated at 10.0 kV with an energy-dispersive X-ray spectroscopy (EDX) operated at 15 kV. The diffuse reflection of absorption spectra of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, and $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ was obtained using an Optizen 3220 UV spectrophotometer. The photocurrent density-voltage characteristics of the thin film solar cell were obtained under one-sun illumination (AM 1.5G, 100 mW cm^{-2}) using an ABET Technologies (USA) solar simulator with an irradiance constancy of $\pm 3\%$.

3. Results and discussions

X-ray diffraction (XRD) revealed that the observed peaks corresponded to rhombohedral Bi_2Te_3 (JCPDS, 73-2036) and the XRD

Fig. 2 XRD patterns of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ powder composites. XRD data for comparison of bismuth telluride percentage in cadmium telluride.

pattern matched that of the JCPDS-89-3011 for the cubic CdTe in planes 200 and 111,²³ with a composition ratio of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$, $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, and $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$. The crystalline nature of Bi_2Te_3 and CdTe indicates the broadening of the XRD peaks in the form of nanoparticles.²⁴ The XRD peaks suggest that the size of the $\text{Bi}_2\text{Te}_3/\text{CdTe}$ particle material is small ranging from 200 to 250 nm, which was observed from the broad peaks.²⁵ Interestingly, Fig. 2 shows that for $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, the XRD peaks corresponding to Bi_2Te_3 are more intense than those corresponding to CdTe, whereas for $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$, the peaks corresponding to CdTe are dominant. The XRD pattern of $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$ closely matches that of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$. This suggests that the crystalline phase ratio between Bi_2Te_3 and CdTe can be controlled by optimizing the ratio between Bi_2Te_3 and CdTe.

Transmission electron microscopy (TEM) of annealed $\text{Bi}_2\text{Te}_3/\text{CdTe}$ revealed the formation of nanorods with sizes in the range of 100–250 nm (Fig. 3(a)). Fig. 3(b) clearly shows the core shell nanostructure of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$. The selected area electron diffraction (SAED) pattern in Fig. 3(c) and (d) revealed the crystalline structural complexity and the fringes of CdTe with a lattice spacing of 0.35 nm corresponding to the (111) cubic planes of CdTe crystals (as shown in Fig. 3(c)),^{26,27} and Bi_2Te_3 has a lattice spacing of 0.13 nm corresponding to (125) trigonal planes. $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ clearly shows nanorod formation (Fig. 4(a) and (b)), whereas formation of nanorods does not occur in samples $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ and $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$. In Fig. 5, the field emission scanning electron microscopy (FESEM) also reveals a morphology of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ exhibiting nanorod formation. The colloidal morphology was observed in the TEM and the

Fig. 3 (a) & (b) Core/shell nanostructure of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$; (c) & (d) electron diffraction (SAED) shows the crystalline structure of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ in sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$.

Fig. 4 TEM images of powder samples of (a) $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ and (b) $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$.

Fig. 5 FESEM morphology of the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ having nanorods approximately 240 nm in size.

Fig. 6 EDX spectrum of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ sample.

outer morphology of the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ was observed by FESEM, which show that nanorods, approximately 240 nm in size, are present in the sample. The atomic ratio of Te to Bi to Cd obtained from the quantitative analysis of Te, Bi, and Cd in the EDX spectrum has an atomic weight percentage ratio of 40.90 : 9.99 : 49.11 and a weight percentage ratio for Te, Bi and Cd as 40.69 : 16.27 : 43.04, respectively, indicating that the ratio of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ is similar to the 25 : 75 ratio shown in Fig. 6.

The transmittance and reflectance shows the structure of the nanorods. In Fig. 7(a), the transmittance image obtained using an advanced polarization microscope shows the structure of nanorods with a $400\times$ magnification. Fig. 7(b) presents the reflectance image, showing the dark-green colored core spots of Bi_2Te_3 inside the orange colored CdTe shell.

The energy band gap of the sample was obtained at different ratios. In $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$ sample, the bismuth telluride ratio is equal to that of CdTe. The energy band gap was 1.76 eV due to doping, resulting in a higher band gap. In combination with $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, the proportion of bismuth telluride was greater than that of CdTe, resulting in a lower band gap of 1.25 eV. This shows that the concentration of bismuth telluride affects the energy band gap of cadmium telluride, which leads to a decrease in the efficiency of solar cells; however, in $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$, the ratio of bismuth telluride, influencing the energy band gap of CdTe, was very low ($\approx 0.5\%$), such that the

energy value of the sample was equal to the standard band gap of CdTe (1.44 eV).^{28–31} This shows that bismuth telluride with a ratio of $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ does not affect the band gap of CdTe. Bi_2Te_3 , which exhibits thermoelectric properties, only supports the increase in the solar cell efficiency and does not

Fig. 7 (a) Transmittance image of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ nanorods and (b) the reflectance image of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ nanorods.

Fig. 8 The energy band gap graph of samples (a) $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$, (b) $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, (c) $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, and (d) CdS layer in the fabricated device.

affect the band gap in the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$. Moreover, $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ has a band gap of 1.45 eV, as shown in Fig. 8. The band gap of CdS is 2.41 eV, which is similar to its standard band gap.

The effect of Bi_2Te_3 in the photoanode on the charge recombination kinetics was investigated by analyzing the I - V characteristics under sunlight at room temperature. Fig. 9 shows the output current and voltage to determine the efficiency of the solar cell. The calculation was performed as follows:

$$\frac{V_{oc} \times I_{sc}}{\text{surface area}} = \text{watt/cm}^2$$

Fig. 9 Light irradiation (one sun) graph showing duration-dependent I - V characteristics of the device.

$$\frac{10\,000 \times \text{watt}}{\text{cm}^2} = \text{watt/m}^2$$

The intensity of light was 700 watt per m^2

$$\eta(\%) = \left(\frac{\frac{\text{watt}}{\text{m}^2}}{\text{light intensity}} \right) \times 100$$

Bi_2Te_3 , with a large thermoelectric figure of merit (ZT), is defined as $\sigma S^2 T/k$, where σ is the electrical conductivity, S is the Seebeck coefficient or thermopower, T is the absolute temperature, and k is the thermal conductivity. Bi_2Te_3 has an enhanced ZT , a high Seebeck coefficient, an increased electrical conductivity, and a low thermal conductivity. The formation of acceptor and donor levels in the CdTe samples is associated with Bi concentration. The interdiffusion of Bi-doping with CdTe solar cells at lower concentration of Bi-doping makes Bi_{Cd}^+ to act as a donor. Therefore a higher J_{sc} in the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ was achieved as compared to that in the other concentration of Bi_2Te_3 . This type of behavior is the mechanism of band bending at the GBs for CdTe solar cells with Bi_2Te_3 .³² Large amount of positively charged Bi_{Cd}^+ donor accumulated near the GBs makes the band bending to occur. The photogenerated electron-hole pairs due to charge separation near GBs cause band bending. Electrons are attracted towards the GBs core (Bi_{Cd}^+) and flow through GBs, whereas the holes are transported through Cd to the back contact. A higher concentration of Bi_2Te_3 generates less power, thus lowering the efficiency. The efficiency was calculated for the combination of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ and $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$,

Table 1 Summary of the photovoltaic properties of $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$, $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ and $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ at 40 °C

Condition	V_{oc} (mV)	J_{sc} (mA cm^{-2})	FF	η (%)
$(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$	419	7.273	29	0.89
$(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$	413	8.012	33	1.09
$(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$	423	10.34	51	2.27
$(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ at 40 °C	535	16.66	54	4.85

where the higher concentration of Bi_2Te_3 makes the device unusable as a solar cell. Fig. 9 shows that $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ has J_{sc} less when compared to the J_{sc} of $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$, denoting that the concentration of Bi_2Te_3 affects the efficiency of the solar cell. Carrier (holes) concentration in $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ and $(\text{Bi}_2\text{Te}_3)_{50}(\text{CdTe})_{50}$ decreases with the increase in Bi_2Te_3 weight ratio resulting from the lower antistructure defects due to the large difference in the electronegativity between Bi and Te. This causes a decrease in the electrical resistivity and Seebeck coefficient. As the concentration of Bi_2Te_3 is higher, the cells lose capability as solar cells and power conversion gets reduced. This impact results in lower J_{sc} and V_{oc} . $(\text{Bi}_2\text{Te}_3)_{75}(\text{CdTe})_{25}$ has J_{sc} of 7.273 and V_{oc} of 0.41 mV with a lower fill factor of 29, which implies an efficiency of 0.89%. $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ is observed to have higher J_{sc} when compared to that for other concentrations. The band gap of CdTe is not affected by the concentration of Bi_2Te_3 in $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$, thus having higher J_{sc} and V_{oc} than the other two concentrations. Under conditions when the front side is illuminated, the power conversion efficiency of the solar cell with the FTO back contact was 2.27% with $V_{oc} = 0.42$ mV, $J_{sc} = 10.34$ mA cm^{-2} , and FF = 51.87% (Table 1).

The sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ shows a better efficiency when kept at 40 °C on a hot plate, similar to the temperatures found in tropical regions. When the sample reaches 40 °C, the I - V characteristics of the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$ show an increase in the power conversion efficiency. As the temperature increases in the fabricated solar cell, the overall power conversion efficiency increases approximately by 2.5% in the presence of Bi_2Te_3 in the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$. This shows that bismuth telluride in combination with cadmium telluride exhibits its thermoelectric property.³³ This response to temperature suggests that bismuth telluride will make a huge difference in the solar cell efficiency in the near future. At 40 °C, the overall power conversion efficiency was 4.8%. The overall efficiency was increased by 24% when Bi_2Te_3 is in the composition ratio of 25% with CdTe.³⁴

4. Conclusion

$\text{Bi}_2\text{Te}_3/\text{CdTe}$ nanorods were synthesized using a wet chemical method. XRD and TEM revealed the mean particle size of $\text{Bi}_2\text{Te}_3/\text{CdTe}$ material; XRD showed that an improvement in the crystallinity of the sample results after heat treatment. TEM revealed the formation of rod-shaped nanoparticles. Polarization microscopy revealed the presence of Bi_2Te_3 and CdTe confirming that Bi_2Te_3 and CdTe are in the form of core shell nanorods. The efficiency of the sample $(\text{Bi}_2\text{Te}_3)_{25}(\text{CdTe})_{75}$

increased by 24% with respect to increase in temperature. The present study shows that $\text{Bi}_2\text{Te}_3/\text{CdTe}$ doping can enhance the efficiency of the thin film CdTe solar cells.
